ABSTRACT | Data is ubiquitous in the 21st century, we voraciously create and consume it, and it can be the driver of innovation and the lens through which we view the world. But data is a slippery, shapeshifting material that can take a myriad of forms which makes it challenging to engage with in a critical manner. This paper explores how design can address the challenge of revealing complex and sometimes hidden relationships with data from the perspective of six individual pieces that have been created as part of two exhibitions. The first project entitled There Be Dragons commissioned five pieces from artists/designers that challenged them to represent data in a way that was meaningful to their lived experience of being a creative practitioner. The five responses sought to untangle personal relationships with data through the application of techniques such as interaction, storytelling, and wayfinding. The Picture Your Poisons piece was created by two of the authors and related to the previous work as it gave form to highly personalised data about cancer treatments through the medium of glass. The paper will reflect on the body of work from the perspectives of the authors as both active agents in shaping the first project and as creators of the second piece. The combination afforded insight into the production of creative work for public exhibition together with the requirements that exhibition places on this process. The subsequent interpretation has identified three emergent themes: performance and participation; rethinking value and representation – making data physical and explicit.

1. Introduction

In 2017 the Economist published an article claiming that, “The world’s most valuable resource is no longer oil, but data” (The Economist, 2017). In the years since then, a great deal has been written about the role that data is playing in shaping the world. In this paper, we look at this often daunting and intractable global topic on a smaller scale, through the lens of the lived experience of the creative practitioner. In this paper, we present reflections on two examples of creative projects that dealt with this topic, and the process of producing them. The first was an exhibition presenting five works; *There be Dragons: Navigating the uncharted data territories of creative practice*. The second is a work titled *Picture Your Poisons*, an artistic project that aims to make scientific and medical data more accessible and impactful to the public. This work was exhibited as part of a larger exhibition. The paper considers themes emerging from these creative works, and we reflect on the development and curation of creative exhibitions as a research method.

2. The Exhibition Contexts

2.1 The Backdrop of Creative Informatics

Creative Informatics was an ambitious research and development programme based in Edinburgh, aiming to bring the city’s world-class creative industries and technology sector together, providing funding and development opportunities that enabled creative individuals and organisations to explore how data can be used to drive ground-breaking new products, businesses and experiences. Creative Informatics nurtured local talent through five key funding programmes and regular events that supported Edinburgh’s creative industries to do inspiring things with data. One of these funding programmes had the aim of bringing academics and industry together in order to break new ground and establish how technology could benefit the creative industries in the future. It was under this initiative that the *There be Dragons* work was produced. The other project discussed was a collaboration between two of the researchers working on the Creative Informatics programme.

Whether implicit or explicit, data plays a role in the work of creative practitioners and artists. From a commercial perspective, even the smallest creative enterprise can benefit from knowing more about their customers, stakeholders and audiences and about wider trends that could influence their future planning. Data comes in many forms, whether it is generated from within the creative practice itself or alternatively whether it comes from an external source. For example, data is collected about creative practices and individuals for use by other agencies, such as to inform government policy and to develop strategies to support creative practice at a wider level. In considering the value produced by data, Speed & Oberlander (2016) assert that creative practitioners can design from, with and by data. For example, design *from* data might use measurable data that can be processed to make it useful; *with* data could involve making use of live data streams or feedback to create interactive designs; and *by* data involves a situation where data itself, supported by an algorithm, will become a designer. Bound up in such an entanglement of the uses of data and the value it may or may not generate, is the question of how data impacts on the lived experience, and the identity, of being a creative practitioner. The mechanism of exhibition was chosen as a catalyst for exploring these issues, foregrounding the experience of being a working practitioner.

2.2 Exhibition as Research Method

As researchers, we had three main aims with the development of these exhibition works. Firstly we wanted to investigate how creative and artistic practitioners understand and articulate the role that data – a complex and multi-faceted concept – plays in their working lives. Secondly, we were interested in design methods and approaches around co-creation, curation and collaborative exhibition design. Thirdly, the projects acted as public engagement activities, aimed at both the general public, and also a particular set of stakeholders. In this latter case, the works acted as stimulation and provocation to inform further

research investigations into the role of data-driven technologies and the challenges of accessing and using data for creative industry participants of all scales, especially small businesses, freelancers and individual practitioners. In this paper we mainly focus on reflections on the first two of these aims.

There be Dragons: Navigating the uncharted data territories of creative practice was funded directly by the Creative Informatics project. It focused on the form and nature of data and specifically addressed the question of how data might best represent the lived experience of creative practitioners. A brief was set by the authors, and five creative practices were selected after a review process to develop their submitted concepts to be part of the final exhibition. The brief was intentionally open and encouraged respondents to

imagine future possibilities for data as well as considering how it exists today. To support this approach practitioners took part in a series of workshops, run by the authors over the six-month development period. To further coordinate the development of the individual pieces and to ensure the overall coherence of the exhibition, a curator from New Media Scotland, an agency fostering artist and audience engagement with all forms of new media practice, was appointed. The curator provided an important point of contact for the practitioners and – critically – was independent of the authors.

The second event was the centenary exhibition of Visual Arts Scotland at the Royal Scottish Academy in Edinburgh. As part of the larger exhibition, the work entitled *Picture Your Poisons* was created by two of the authors and sought to make visible the normally hidden data associated with a medical procedure.

All six pieces created an opportunity to both engage with and reflect on the nature of data through the creation of physical artefacts and the process of making (Huron et al, 2023). In the first instance, the authors were engaged throughout the production process and worked with the individual creatives as they developed their ideas from initial concepts to a final exhibition piece. In the second instance, it was two of the authors who produced the work for the exhibition. These roles provided a unique insight into the role and representation of data during the production process and how audiences responded to the final exhibition pieces.

3. There Be Dragons: Navigating the Uncharted Data Territories of Creative Practice

The motivation of the *There Be Dragons* project was to critically reflect on the types of data that practitioners considered to best represent their experiences of producing creative output. These individuals and groups were attempting to wrangle the disruption of the digital shift, with its increased pressure to continuously acquire new technical skills, and to build upon existing proficiencies for creative production, collaboration, innovation and dissemination (Helgason et al, 2023).

Up to this point much of the data used to describe what is referred to as the creative industries has been at a systemic level. For example, in the Spring budget of 2023, the UK Chancellor declared that the creative industries were a growth industry. This served as recognition that the sector had generated over £100 billion in revenue, representing over 10% of the UK economy and providing 2.29 million creative industry jobs. But behind these statistics lie real people, producing creative output in times of undoubted challenge. The aim of the *There Be Dragons* project was to explore how creative practitioners saw themselves and what data they considered to best reflect their own lived experience. The approach complemented the human-centred approach of the Coast to Coast project (Smyth & Delaney, 2023), also undertaken as part of Creative Informatics which conducted a visual and textual study of creative practice that focused on individual practitioners in Scotland and Northern Ireland.

The work reported in this paper contributes to the overarching goal of giving a voice to practitioners in terms of how they identify as creatives while acknowledging that it is a very personal and contextual endeavour that is set against a backdrop of the seemingly continuous shifting sands of economic and social change.

The *There Be Dragons* project started from the premise that data can empower creative businesses to do more and to do it better. Data can be used *for* creative practice, *with* creative practice, and to tell us *about* creative practice. However, coping with data is not a simple or straightforward activity. It has to be collected, analysed, visualised, understood and communicated (Sanches et al 2022). There are ethical and privacy issues to consider. The project aimed to investigate and untangle some of these messy issues in order to build a more representative picture of the role that data plays in the life of the creative practitioner. A key objective was that the project should speak to and for the creative community, so it was critical to harness the creative and artistic skills of the community itself in a collaborative design and exploration process.

As a source of inspiration, the artists were encouraged to consider future scenarios or "imaginaries" as a method to speculate about data. This technique gave permission to decouple from many of the practical issues associated with data and to give a freedom to their imagination as they explored the relationship between data and creative practice. It was hoped that this approach could reveal insights for further discourse and create outputs that would engage a wider public audience in an accessible way. The result was that each of the artists' responses provided an insight to their complex and sometimes very personal relationships with data and how it was seen to reflect their practice.

3.1 The Exhibition Pieces

The five works that comprised the *There Be Dragons* exhibition are described in the following section.

When Do You Give Yourself Away? by Theodore Koterwas

The motivation of this work was to examine aspects of daily experience that often go unnoticed, with a particular focus on data as it relates to the body. The installation took the form of a large screen that displayed coloured patterns and shapes that responded to the pulse and galvanic skin response of people who placed their hands on two pads of medical gel that were attached to the screen (Figure 1).

Figure 1. When Do You Give Yourself Away?

By physically engaging with the work, the artist wanted to explore the idea of "giving away" data and how the normally hidden physiological data could be reimagined as a public performance. The experience was further enhanced through floor-based speakers that literally shook the ground beneath the feet of participants.

The overall effect was that intimate personal data coming from the body was being magnified and displayed in full view. The piece sought to explore how personal data might be externalised and, if personally identifiable, what this might mean for data that is more intimate and internal.

Doing Data by Elke Finkenauer

This response took the form of experimental sculptures that used strategies inspired by data analysis to create physical forms that explored parallels between the worlds of making and data (Figure 2). In essence, the work was a metaphor for data gaps and ways to handle what slips between the cracks of data analysis.

Figure 2. Doing Data sculptures.

Inspired by the idea of data that gets left out or ignored, the practitioner created a database of materials from her studio. One of the categories was “material scraps,” from which items were selected to create a series of configurable sculptures. The processes and materials were documented in infographic sheets as part of the exhibit (Figure 3). At the core of the work was an exploration of tension between data-driven systems and structures, and things that don’t fit.

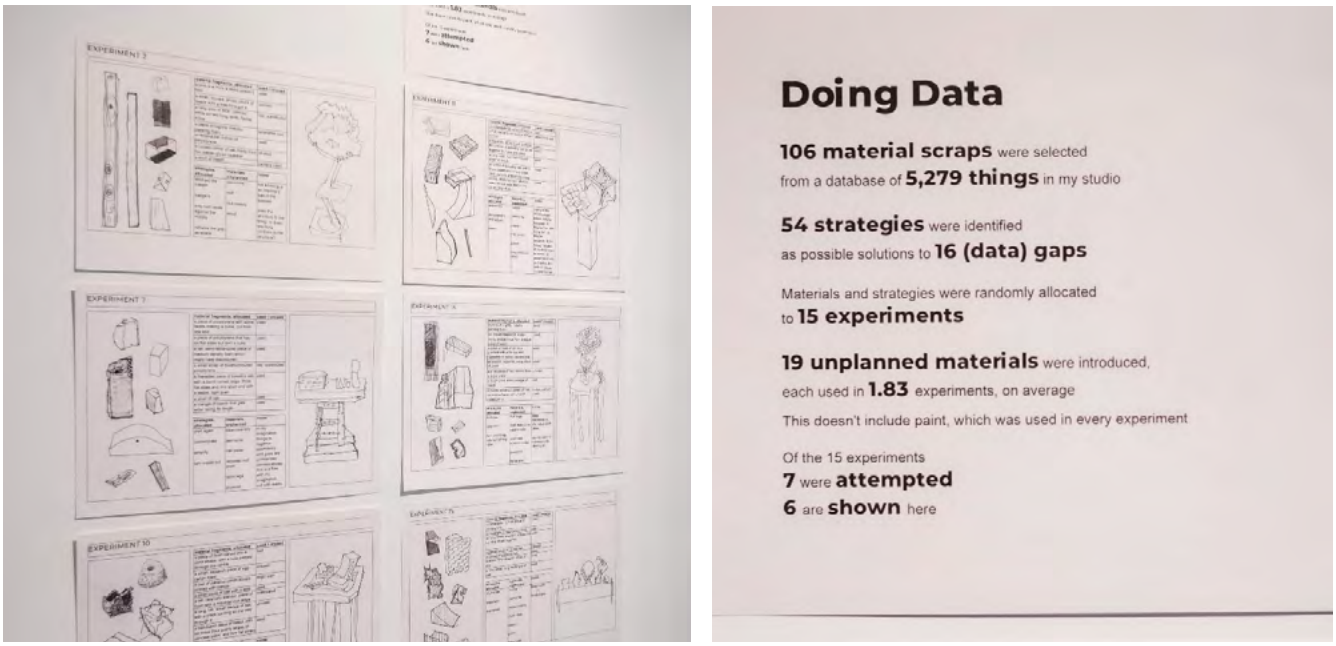

Figure 3. Doing Data Infographic sheet.

Privacy Wizards or Data Thieves? by More Fun With Games, in partnership with Ray Interactive, Cameron Hall and Two Rats Press

Through the use of an interactive walking adventure, this piece explored the idea of personal data and how much participants were willing to reveal of themselves to discover new information. Based on the premise of a “shadow self” that was created by a person's online presence, the setup of the game assigned participants to a character class, either Privacy Wizards – people with relatively data-secure habits – Everyday Rangers in the middle, or Data Thieves – people using services that might detect a lot of their data.

The set-up process engaged participants in a playful dialogue that encouraged them to provide personal information in order to take part in the walking game. This formed the basis of a later conversation about the unknown nature of data that is revealed during the typical sign-up process to a mobile app.

Figure 4. The walking game; Unveiled Edinburgh, part of Privacy Wizards or Data Thieves?

The walking game was called Unveiled Edinburgh (Figure 4) and required the players to engage with the local area, and discovering something, or see something familiar in a new way. Through participation, the piece sought to highlight how people use data to "feed" their digital shadow self, and through the provision of alternatives, the work encouraged discussion of data, privacy and manipulation, together with face-to-face social connection.

Enough is Enough by Amy Dunnachie, Lorna Brown, Lynne Hocking – on behalf of Applied Arts Scotland

This piece was a collaborative, participatory installation laid out on a tabletop grid of tasks and accompanying tactile tokens that were used to indicate specific activities and tasks that reflected the daily work of creative practitioners. The tasks were categories of creative work and revealed the broad range of possibilities associated with creative production. For example, research new materials, share skills, go for a walk, read for fun, do the tax return, meet clients or research exhibition venues (Figure 5).

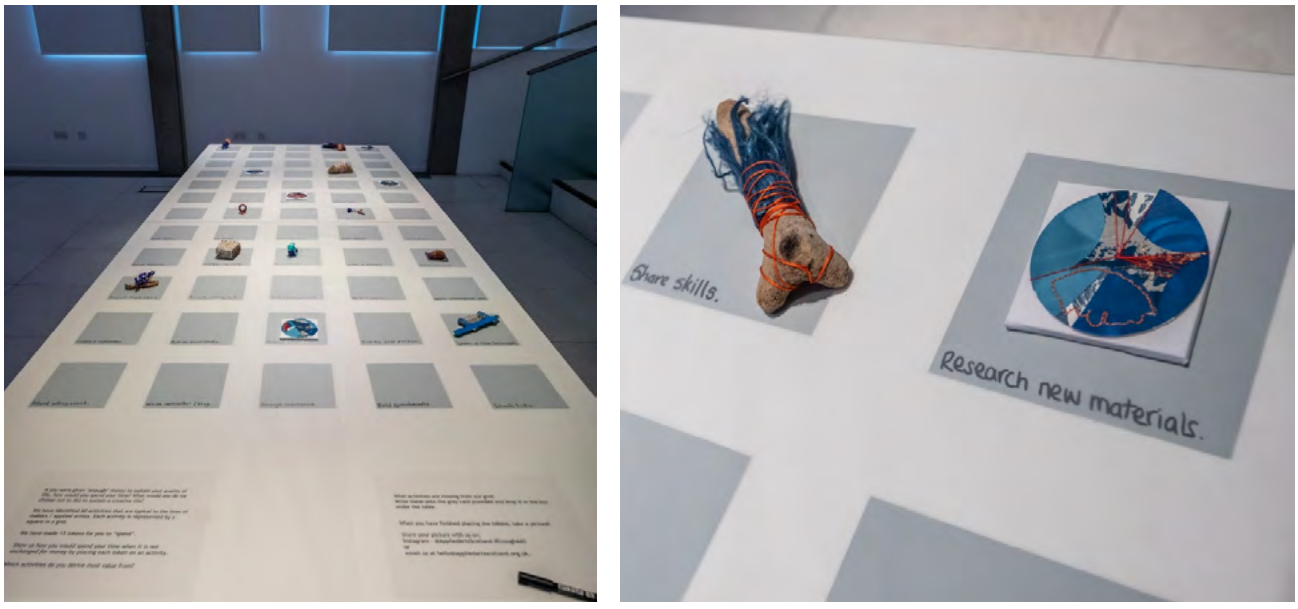

Figure 5. Enough is Enough.

Visitors could place the tokens on the grid of tasks, signalling their affinities and priorities, and creating a shifting picture of contemporary creative practice. The act of selecting categories also acted as an opening of discussion about creative work and livelihoods.

As well as giving a current snapshot of making practice, the installation invited people to think about how creative practice might be different. For example, if you didn't have to think about financial values or income streams, how would your creative choices change? What would be made? How would the values change?

People could add their own tasks and ideas to the grid, so it was also a way to gather data on other people's value systems around being a creative practitioner or running a creative business."

Cloud by Melanie Frances

The piece (Figure 6) was more abstract and consisted of a series of data fragments that revealed multiple narrative threads centering on the operation of a fictitious data cloud. The format acted as both a provocation and a metaphor for how data can mean different things to different people and can be read in different ways by different people. The work sought to find ways of exploring that diversity of viewpoint and the plural nature of data.

Figure 6. Cloud.

4. Picture Your Poisons by Inge Panneels and Caitlin McDonald

This work is distinguished from the previous exhibition pieces in that it was created by two of the authors blending their unique artistic backgrounds as a glassmaker and a mixed-media memoirist to represent unique, highly personalised data about one of the author/artist's cancer treatments. Their prior collaborations on *There Be Dragons* and its sister research project about data used in creative industries policymaking, *Detecting Dark Matter Data,* informed the artists' intentions to use historical medical data in the creation of *Picture Your Poisons,* as well as the subjective, experiential lens that naturally infuses all self-portraiture. The artwork was selected for display as part of a retrospective exhibition organised by Visual Arts Scotland, as well as displayed among works bridging the artificial divides between the arts and sciences in the Edinburgh Science Festival, the UK's largest science festival (Figure 7).

Picture Your Poisons presents an intimate portrait of a cancer treatment journey as experienced by one of the artists. Nearly 1 in 2 people born in the UK in 1961 will be diagnosed with some form of cancer during their lifetime (Cancer Research UK, n.d. a), including one in seven women with breast cancer (Cancer Research UK, n.d. b). The glass casts featured in *Picture Your Poisons* ground viewers in the real-world material origins of systemic anti-cancer treatments through the specific lens of one patient's course of treatment. Each of the six glass casts and one wax mould constituting the artwork represents the substance from which a type of cancer treatment was originally derived in nature, including mouse-derived immune

proteins, yew tree bark, soil bacteria discovered in Tuscany, the elements carbon and platinum, and radioactive energy. These treatments are usually discussed in a clinical context with reference to their bodily effects on the patient, leaving out the rich history of their discovery and development. By materialising each treatment, the casts allow viewers to explore data which is more usually presented in an abstract, clinical context through a striking visual medium that elicits an emotional as well as a cognitive response (Figure 7). The artwork encourages the viewer to explore aspects of the patient experience relating to bodily autonomy, selfhood, and dis/empowerment in medical contexts by confronting them with the disembodied partial body casts of the affected breast.

The difference between medicine and poison is largely one of dosage (Grandjean, 2016). Substances which in one context are deadly (and indeed, used as weapons, such as the mustard gas from which the chemotherapy cyclophosphamide is derived) are also life-saving. *Picture Your Poisons* explores this relationship using glass, a substance of many dualities: brittle yet strong, transparent or opaque, malleable yet firm. Glass is forged in a transformative process of great stresses on the raw materials, and similarly, cancer survivors endure treatments which radically transform their bodies in order to survive.

Figure 7. Picture Your Poisons (Photo by Caitlin McDonald).

5. Discussion and Reflection

5.1 The Question of Data

Data is ubiquitous in the 21st century, we voraciously create and consume it, it can be the driver of innovation and it can replicate the world through digital twinning (Ganguly & Venkatasubramanian, 2022). Data has become a lens through which we view and seek to understand reality. But data is a slippery, shapeshifting material that can take a myriad of forms which makes it challenging to engage with in a critical manner. It hides in plain sight but remains resistant to classification. The reality is that data is never neutral, it is always gathered by stakeholders, for a given purpose using specific tools. This illusion

regarding the neutrality of data has been referred to as the "commodity fiction" of data by Gitelman et al (2013). This idea has been further developed by Sanches et al (2022) who report on the growing body of design research that shows that data is neither immaterial, nor finished but is instead co-produced by many entangled factors including people, context and the sensors, analysis and display techniques employed. It was against this backdrop that the work reported here sought to shed light different forms of data and how that data might best reflect the eclectic nature of creative practice.

6. Emergent Themes

The *There Be Dragons* project offered the authors a particular insight into the production of creative work for public exhibition. The authors set the brief and selected the creative practitioners and while not producing the work themselves, the authors were at the centre of the process and were undoubtedly active agents in shaping the project. The introduction of a curator contributed to the overall coherence of the exhibition and alleviated some of the tensions over adherence to the brief that emerged during the various workshops. An independent writer was also employed in the second half of the production phase to interview each of the creatives in order to better understand their experience of being part of the project. The resulting publication was available during the exhibition (Horne et al, 2023).

While it is acknowledged that this does not constitute an exhaustive or indeed controlled environment, the insights gained from the *There Be Dragons* exhibition, in particular the representation of hidden data, went some way to informing the approach of the authors who created the *Picture Your Poisons* work.

Based on the authors' interpretation, three main themes emerged from the work:

6.1 Theme: Performance and Participation

All of the work described previously was designed to be experienced in a public gallery or exhibition setting. As a way of attracting people, some of the pieces employed an explicitly performative style in terms of how they either represented data or encouraged people to interact with the data, or as a means to reveal hidden data and provoke further discussion.

For example, *When Do You Give Yourself Away?* used abstract colours and sound to represent physiological data that was harvested through physical gel pads which people touched. The abstract nature of the representation actively encouraged exploration through movement as people tried to apply meaning to the data. The performative nature of the work was a natural draw to visitors at the exhibition.

A different perspective on performance was provided by the *Enough is Enough* work. This piece was explicitly designed to be performative where individuals moved counters on a tabletop grid to prioritise the daily work of creative practitioners. The act of making these choices visible acted as a catalyst for discussion and encouraged participation.

Finally, the work entitled *Privacy Wizards or Data Thieves?* adopted a deliberately performative style by incorporating an interactive walking adventure to highlight issues around data privacy. Through the use of a facilitator/guide participants in the adventure were encouraged to discuss how much data about themselves they were willing to provide in order to discover something new by participating in the walk.

6.2 Theme: Rethinking Value

Data is about choices; making selections about what data is gathered and for what purpose, how, where and when it is gathered and by whom. The work of Sanches et al (2022) emphasises these complex entanglements around the gathering of data and builds on the growing body of design research that shows that data is neither immaterial, nor finished but is instead co-produced by many entangled factors

including people, context, and the particular sensors, analysis and display techniques employed. Each of these factors contributes to the value placed on data. This view of data draws from the concept of diffraction as presented by Barad (2007) which prioritises what is referred to as the "entanglement of the apparatus of production".

The work entitled *Doing Data* explicitly interrogated the notion of value attributed to data by focusing on gaps in data, the forgotten or hard to reach data that becomes somehow devalued because of its inaccessibility. By explicitly documenting what was referred to as material scraps, the piece presented five configurable sculptures representing data that would have otherwise been lost. By reasserting the value of these materials, the work sought to demonstrate how the production of data is both a complex and multi-stakeholder endeavour.

6.3 Theme: Representation – making data physical and explicit

The ubiquitous nature of data makes it challenging to pin down and engage with in a critical manner. The approach taken in this paper has been to employ exhibition as a research method from which to explore methods of representing data and in particular how design can address the challenge of revealing the complex and sometimes hidden relationships with data through the making of physical artefacts.

For example, the piece entitled *When do you give yourself away*? translated normally hidden physiological data into abstract colours and sounds that created a performative experience in the exhibition setting. The *Enough is Enough* work encouraged the audience to engage in conversations as they prioritised a series of activities that reflected the daily work of creative practitioners, through locating tokens on a tabletop grid.

Cloud explored the multifaceted nature of data through the use of interconnected narrative fragments that revealed how different people might respond to the ever present nature of data in an imagined future. By exploring that diversity of viewpoint and the plural nature of data the work interrogated how data can mean different things to different people.

The most explicit representation of data that is normally hidden was illustrated in the *Picture Your Poisons* work which used the medium of glass to represent and make visible the treatment of breast cancer. The visualisation of a series of anti-cancer treatments through a series of glass casts and their concomitant labels which mimicked the safety data sheet enclosed in drug packaging, attempted to reveal data that more normally resides in a clinical context and thereby provoke both an emotional and cognitive response in the viewer.

7. Conclusion

This paper presents a description and discussion of two related exhibition projects, together comprising of six individual creative artworks, that addressed the relationship between data and creative practice. The authors' roles in this process were varied; as instigators, curators, researchers, and as creative artists. From this range of perspectives the paper presents our interpretation of the themes that emerged from the exhibited works. It also argues that exhibition production can be a valid and fruitful design research method for interrogating intangible concepts that impact on lived experience. In this case, the act of creative making, and the demands of public exhibition, supported deep reflection on the meaning of data and how it relates to life as a creative practitioner.

About the Authors:

Michael Smyth is a Professor in the Interaction Design Research Group, Edinburgh Napier University. He researches and teaches in the fields of interaction design and human computer interaction and is intrigued by the space between people and technology.

Inge Panneels is an artist and Lecturer in Digital Media at Edinburgh Napier University. Her research focuses on the creative industries, circular economy, sustainability, design for change, digital media and mapping.

Caitlin McDonald is a researcher based at the University of Edinburgh with a focus on creative industries policy and digital ethics, and an artist whose work exploring personal experience through the lens of data has been featured in several international exhibitions.

Ingi Helgason is a lecturer at Edinburgh Napier University. Her research interests include user experience, interaction design, creativity, storytelling, speculative design approaches and interactions with creative and marginal archives.

Acknowledgements: The authors would like to acknowledge the work of Mark Daniels of New Media Scotland whose creative direction and curation made the exhibition possible.

This research was funded by the United Kingdom's Arts Humanities Research Council (AHRC) Creative Informatics: Data Driven Innovation for the Creative Industries (Grant Ref: AH/S002782/1).

KEYWORDS | AI-DRIVEN DESIGN, HUMAN-COMPUTER INTEGRATION, ETHICAL IMPLICATIONS OF AI DESIGN, DESIGN EPISTEMOLOGY, COMPUTATIONAL CREATIVITY

ABSTRACT | AI's ability to process vast data sets, predict trends, and develop innovative solutions makes it experienced and perceived beyond a simple tool, fostering changes in the design domain in both the theoretical framework and practical applications. This paper aims to explore the significant transformation within the design discipline, increasingly influenced by the integration of Artificial Intelligence (AI) in creative processes.

The contribution critically examines the theoretical and methodological challenges brought by AI, particularly regarding generative content creation. Through the analysis of various aspects of AI integration in design – from how AI algorithms are influencing aesthetic choices to their role in automating and enhancing creative processes – the paper discusses the evolving role of the designer in an AI-integrated environment, contemplating the balance between human creativity and machine intelligence.

This contribution aims to discuss AI as a transformative force that is redefining design processes, encouraging designers to embrace new creative challenges and opportunities in the AI era. Through this exploration, the paper aims to contribute to the broader discourse on the evolving relationship between technology and creative industries, particularly focusing on the dynamic interplay between AI and design.

1. Introduction

Digital technologies permeate every layer of society, mediating interactions between subjects and objects, thereby accelerating a profound transformation of the world, which necessitates a new ontological and epistemological framework across various disciplines (Dufva & Dufva, 2019; Kraus et al., 2021). Enabling technologies, brought by digital transformation (DX), are embedded in creative and business processes, intervening in producing value across numerous human activities, with design, production, and consumption processes directly implicated. The necessity for design to recognise the interdependence between humans and their surrounding environment, encompassing natural, artificial, and digital entities becomes crucial in the era of digital transformation (Escobar, 2018; Forlano, 2017; Irwin, 2015). Design must address the challenge of harmonising technology with the global ecosystem, acknowledging that this transformation is deeply rooted in physical, ecological, and social contexts. It is increasingly important to consider the ethical and environmental impacts of activities, as well as technological innovations.
As early as the first decade of the new millennium, Sellen, Rogers, Harper, and Rodden (2009) reflected on emerging paradigms in human interaction with technology, reshaping the boundaries between computers, individuals, and artifacts. The advent of intelligent networks has amplified this dynamic, with non-human entities assuming an increasingly active role in decision-making processes, establishing a symbiotic relationship where humans and software operate collaboratively.

Artificial Intelligence (AI) stands out as one of the most powerful and discussed technological innovations in our era, particularly regarding its potential impact on creative processes (Lubart, 2005; Daniele & Song, 2019; Fujita, 2018; Mazzone & Elgammal, 2019), and the ensuing ethical implications. AI is increasingly permeating design professions due to its proficiency in executing repetitive or challenging tasks for humans, such as analysing and extracting big data, forecasting outcomes, and even generating new content (Anantrasirichai & Bull, 2022).

Recently, innovative tools have utilised Generative Adversarial Networks (GANs) to generate new, previously unseen data that learn from and *creatively* use existing data to generate new outputs, significantly influencing the creative stages. These tools are not merely facilitative; they are transformative, offering the potential to reshape methodologies and processes within design and manufacturing, pushing pivotal questions concerning AI's capacity to shape creativity, creation processes, product development, and the audience's engagement with creative activity (Daniele & Song, 2019; Miller, 2020). Despite the undeniable impact of these powerful technologies on numerous human activities, there are also many misconceptions about AI that are perpetuated through the choice of wording, imagery, or analogy (Kurenkov, 2019).

AI is deeply rooted in the data revolution (Tedeschi & Lombardi, 2018) and anchored to mathematical-logical structures that underpin its ability to process, analyse, and interpret vast volumes of data efficiently. Mathematics provides the foundational structures for AI algorithms, while machine learning and neural networks utilise advanced calculations to 'learn' and improve. Concurrently, logic plays a crucial role in AI decision-making, allowing it to evaluate information, recognise patterns, and make choices based on well-defined criteria (Esling & Devis, 2020). Hence, introducing AI in the design domain can expand creative opportunities while introducing new ethical and methodological challenges (Verganti et al., 2020; Weisz et al., 2023), rewriting the relationship between design and mathematics, and between design and computational geometry.

This scenario transcends mere process automation, fostering multidimensional collaboration to explore previously inaccessible domains. It leads to behavioral models no longer confined to human-computer interaction but evolving into human-computer integration (Farooq & Grudin, 2016), a trajectory that envisions a partnership between humans and computers in the context of AI, meriting holistic consideration. In such a context, Artificial Intelligence (AI) emerges as a powerful catalyst for transformation, profoundly influencing socio-cultural, political, and economic dynamics in the contemporary evolution of design. The design field is facing the need to re-examine its foundations in terms of roles, functions, and approaches, and to weave new disciplinary relationships (Ozmen Garibay et

al, 2023). AI's ability to process vast data sets, predict trends, and develop innovative solutions fosters changes in the design domain in both the theoretical framework and practical applications. Particularly, the advancement in image and morphology generation through generative algorithms enables the creation of high-quality, realistic content in very condensed time frames, thus broadening the scope of creative possibilities while presenting significant ethical and methodological challenges.

This paper aims to critically examine the theoretical and methodological challenges brought by AI, particularly regarding generative content creation. It navigates through various aspects of AI integration in design, from how AI algorithms are influencing aesthetic choices to their role in automating and enhancing creative processes. It discusses the evolving role of the designer in an AI-integrated environment, contemplating the balance between human creativity and machine intelligence. Additionally, the paper investigates the ethical and practical implications of AI in design, addressing how AI-driven design approaches are reshaping expectations and redefining standards. Through this exploration, the paper aims to contribute to the broader discourse on the evolving relationship between technology and creative industries, particularly focusing on the dynamic interplay between AI and design.

2. Designing with AI

As the design discipline dynamically co-evolves with technological and societal shifts, experimentation with AI algorithms catalyses a substantial paradigmatic shift (Kuhn, 1962), offering unprecedented capabilities in exploring novel design possibilities (Daniele & Song, 2019; Fujita, 2018). AI is not a single entity, but rather a set of techniques and ideas (Kurenkov, 2019). It embodies a diverse spectrum of technologies and methodologies that can facilitate the creation of efficient solutions (Abd Aziz et al., 2021) and potentially enhance the design process, improving both the quality and functionality of design outputs (Thompson et al., 2016; Xiong et al., 2019).

New tools enabled by AI can invest both the input (design-management-control methods), as well as the output (product performances and meanings) of design processes, potentially revolutionising the way designers approach their work, offering the ability to verify and simulate various design scenarios. This advancement allows designers to predict outcomes and assess the feasibility of their ideas with greater accuracy than ever before. This not only streamlines the design process but also opens up new avenues for creative exploration, changing the way design innovates and delivers value (Magistretti et al. 2019). As AI progressively permeates daily activities, designers are prompted to explore the challenges of working with AI 'as a new design material' (Holmquist, 2018; Dove et al., 2017; Yildirim et al., 2022), considering AI not only as a tool or technology but as an integrated component of the creative process, a perspective that brings with it specific anomalies and opportunities. For instance, AI-driven tools can simulate the environmental impacts of in-progress designs, a capability that aligns with the growing need for sustainable design practices. They can also model user interactions, thereby enhancing user experience design, and evaluate the long-term sustainability of a design, ensuring that products are both environmentally and economically viable in their lifecycle.

AI has reached a significant level of maturity, both as a scientific discipline and as a technology. In recent years, a growing number of studies have focused on examining the challenges, benefits, and potential impacts of AI in achieving the Sustainable Development Goals (Goralski & Tan, 2020; Truby, 2020; Vinuesa et al., 2020). In this regard, the environmental impact of training AI models, particularly large-scale ones, has become a prominent concern (Nishant et al., 2020). The process of developing advanced AI systems, which involves extensive computational power and data processing, results in significant carbon emissions (Wu et al., 2022). This environmental cost raises critical questions about the sustainability of current AI practices (van Wynsberghe, 2021), especially as the demand for more sophisticated and larger models grows.

The integration of AI into design processes has the potential to radically transform the discipline, bringing significant changes across three main key areas:

1. Streamlined Prototyping and Simulation: The advent of AI is redefining design processes, allowing for ultra-rapid prototyping, real-time testing, and fast refinement of design concepts. AI's ability to quickly analyse and simulate various scenarios can enable designers to explore different kinds of proposals and iterate designs in real-time, significantly accelerating the design development process and enhancing its adaptability to changing requirements and user feedback.
2. Enhanced Customisation and Predictive Capabilities: AI's proficiency in dissecting and interpreting user data leads to unprecedented levels of personalisation, allowing designs to be precisely tailored to individual user profiles. Furthermore, AI's predictive abilities equip designers to not only address current trends but also anticipate future developments, thereby future-proofing design outputs.
3. Collaborative Dynamics in Human-AI Interaction: The relationship between human designers and AI systems is evolving into a synergistic partnership. AI's computational strength in processing and analysing large data sets offers insights and perspectives that can - to some extent - augment human creativity. This collaboration has the chance to expand the realm of creative possibilities, enhances problem-solving, and facilitates informed decision-making, merging human intuition with AI's analytical strength.

Despite this shift burgeons unprecedented creative opportunities, it concurrently unveils fundamental challenges (Verganti et al., 2020; Weisz et al., 2023) concerning potential impact on creative and cultural products, which are not simply consumer goods but they act as genuine devices of symbolic and cultural mediation (Branzi, 2007; Kubler, 2008). With AI in creative processes, these products are now being shaped by or within any potential AI's bias and perspectives.

Indeed, the literature widely acknowledges that digital technologies like AI have agency, this means that they transform, translate, distort, and modify the meaning of elements they are supposed to carry (Latour, 2007). In addition, ethical data management, bias mitigation (Harrison et al., 2019; Ntoutsi et al., 2020; Siau & Wang, 2020) and decision-making transparency, as well as designers' role as involuntary and often unwitting 'trainers' of 'learning machines' will probably have a profound impact on the future of design practice. This evolution in design, where the underlying rules and algorithms take precedence over the creation of artifacts, signifies a profound departure from the conventional paradigm of computer-aided design to a realm of digitally mediated design. The implications of this transition are multifaceted and far-reaching. Designers are now required to engage with the complex and often opaque algorithms that drive AI-based tools. This necessitates a deeper understanding of AI technologies, not just as instruments of efficiency or creativity but as active agents that can shape the outcome of the design process in significant ways. This recalls an expansion in the skill sets required for design professionals, with a comprehensive understanding of AI, data analytics, and programming. These skills are essential for effective interaction with AI systems and for leveraging AI-driven insights in the design process. This new dynamic challenges designers to maintain a balance between their creative intuition and the data-driven insights provided by AI. It requires a nuanced understanding of how AI processes and interprets data, and an awareness of how these interpretations can influence design outcomes.

Furthermore, this transition brings to the forefront the broader ethical and cultural implications of design work that need further investigation. In the realm of this contribution, it is important to highlight that systems are fed with data that may carry inherent biases, designers with AI should be (and know how to be) vigilant about the potential for these biases to be reflected in their designs. This raises ethical questions about representation, inclusivity, and the societal impact of design.

In summary, the shift to a digitally mediated design process redefines the essence of design practice. It requires designers to be interpreters and custodians of the complex interplay between human creativity and machine intelligence. This paradigm shift presents an opportunity for designers to explore new creative frontiers, while also imposing a responsibility to ensure that their work remains ethical, culturally sensitive, and socially responsible in an increasingly AI-driven world.

3. Changes and Challenges

The shift from traditional and human-centric design processes to digitally mediated and algorithmically-driven practices demands a critical exploration into the role, value, and nature of human thought, creativity, and ethical considerations within the AI-augmented design landscape. Following this streamline, recent studies in the creative research field, highlight the profound impact of AI on creativity, transforming its five core elements: actor, process, outcome, domain, and space (Wingström et al., 2023). With AI's integration, actors now include both humans and machines; processes are influenced by algorithms; outcomes merge human and AI contributions; domains extend into digital realms; and creative spaces blend the physical with the virtual. In essence, AI is becoming a partner, an extension, a material, and a medium, reshaping the very essence of creative practices (Särmäkari & Vänskä, 2022).

In the 'traditional' design process, creativity dynamically emerges, often marked by 'creative leaps' that transition ideas from conception to realisation (Dorst & Cross, 2001). Designers explore possibilities through iterative sketching, prototyping, and refinement, navigating various solution pathways and overcoming creativity obstacles (Boden, 2004; Cross, 2006; McKelvey & Munslow, 2011; Hopkins, 2021). Moreover, scholars acknowledge that 'traditional' design approaches are deeply rooted in human intuition and experience (Cross, 2004; Lawson & Dorst, 2013; Särmäkari, 2021; Bruce et al., 2002), and the ability to envision beyond the tangible and the explicit through tacit and technical knowledge. Despite its advanced capabilities, AI still lacks essential elements of creativity, such as intention, motivation, self-assessment, and the capacity to interpret outcomes or discern innovation (Davis, 2013; Aoki, 2021; Mitchell et al., 2019). This brings forth the intricate debate surrounding consciousness and whether AI can genuinely manifest it. However, it is essential to note that AI does not necessarily need to be 'intelligent' to contribute to the creative process. Design can still uncover novel and intriguing possibilities through collaboration with AI. This perspective aligns with posthumanist theories, where the creative product is a joint endeavour, co-constructed through the symbiotic interaction between design and AI (Ihde, 1990; Latour, 2013; Rose, 2017).

Hence, while it is not possible to decelerate technological advancement, comprehending it becomes crucial to navigating it in orientation. It is significant, thereby, harnessing the potential of AI to enhance, rather than undermine, the cultural and creative processes intrinsic to design practices. This means recognising the growing influence of the tech-computational domain, advocating collaboration over replacement, studying processes and establishing frameworks that steer technology integration in an informed, ethical manner and are aware of its broader impacts, especially in domains intersecting with cultural and social identity, such as design (Symbola Foundation, 2023).

Those challenges underscore the significance of multidisciplinary collaboration in tackling a multifaceted issue that instigates ontological and epistemological reorientations. The burgeoning weight characterised by the technological-computational realm also envelops the sphere of problem-solving, increasingly entrusted to AI, data, and computational capacity. Consequently, it becomes crucial to embrace the transformation through disciplinary collaboration between the mathematical-computational and design fields to address various emerging questions in this new scenario, which pushes the question: 'What kind of thinking is left to humans in innovation?' (Verganti et al., 2020, p. 224).

3.1 Human-Centricity vs. Algorithmic Design

The integration of AI into design practices marks a significant transition from human-centricity to algorithmic design, a change that presents a wide array of ethical and social challenges. This shift is not merely about adopting new technologies but fundamentally rethinking the design process itself. Design approaches, which have predominantly centred around human intuition, experience, and creativity, are now evolving to incorporate algorithmically-driven methodologies that leverage AI's computational power.

This pivotal shift necessitates a deep dive into several critical areas. First and foremost among these is the ethical management of data. As AI systems rely heavily on data for learning and decision-making, the integrity and fairness of this data become paramount. This recalls the works of Harrison et al. (2019),

Ntoutsi et al. (2020), and Siau & Wang (2020), who pointed out the importance of bias mitigation in AI systems. The risk of AI inheriting and amplifying existing biases present in the data is a significant issue, which, if unaddressed, can lead to skewed and unfair outcomes.

Additionally, the transparency of decision-making in AI-driven design is a crucial concern. As design processes become more reliant on algorithms, understanding the rationale behind AI-generated decisions is essential. This transparency is not only important for the designers to retain control over the design process but also for end-users and stakeholders who need to trust and understand the products created through these methods. As AI takes on more responsibilities in the design process, there is a risk of underestimating the unique qualities that human designers bring to the table like empathy, contextual understanding, and creative intuition that are, as of yet, beyond the reach of AI.

In essence, the integration of AI into design practices is not just about harnessing a new set of tools; it is about striking a balance between the efficiency and capabilities of AI and the irreplaceable value of human insight and creativity. This balance is crucial in maintaining the integrity, ethicality, and quality of design in an age increasingly influenced by algorithmic methodologies.

3.2 Integrating AI in Design Cultures

While the role of AI is prominent in the industrialisation phases of design production processes, its application in the ideational and creative phases remains less explored. This expansion of AI's application requires a careful examination of its potential to contribute to every stage of the design process, acknowledging that AI can offer more than just efficiency and automation and recognising that every stage of the design process is potentially computable.

One of the critical areas in this exploration is understanding the impact of AI on authorship in design. As AI systems can generate design elements autonomously, questions arise about the originality and ownership of such creations. This challenge necessitates a redefinition of authorship in the context of AI-generated content, where the role of the designer may shift from being the sole creator to a curator or editor of AI-generated options. Copyright issues also emerge as AI becomes more involved in creative processes. The legal framework surrounding AI-generated content is still evolving, and there's a need for clarity on how copyright laws apply to designs partially or wholly created by AI (Pasa, 2023). This area requires ongoing dialogue among legal experts, designers, and technologists to establish clear guidelines and standards. Furthermore, the agency of AI in design, where AI systems make decisions or suggest design alternatives, poses a challenge. This situation calls for a balance between leveraging AI's computational power and maintaining the designer's creative control and judgment. It involves understanding and setting the appropriate boundaries for AI's role in the design process, ensuring that AI acts as an enhancer of human creativity rather than a replacement.

Integrating AI into design cultures is not just about adopting a new set of tools; it's about navigating a complex landscape of ethical, legal, and creative challenges. It requires designers to adapt and develop new ways of working, where AI is a collaborator that brings computational power to the creative process, but human creativity, judgement, and ethical considerations remain at the forefront.

3.3 Avoiding the AI Black Box

Addressing the issue of the AI Black Box is critical in the context of design practices. The term 'AI Black Box' refers to situations where the decision-making process of AI systems is opaque (Castelvecchi, 2016; von Eschenbach, 2021), leading to a lack of transparency and understanding about how AI algorithms arrive at certain conclusions or design solutions. This opacity can be problematic, particularly in fields like design, where the rationale behind each decision can significantly impact the final product.

To navigate and mitigate the challenges posed by the AI Black Box, it's essential to prioritise the development and use of AI systems that are transparent and interpretable. This means designing AI

algorithms in a way that their decision-making processes can be easily understood and explained, not just by AI specialists but also by designers and stakeholders involved in the design process. Transparency in AI facilitates a more collaborative and trustful relationship between human designers and AI systems, ensuring that AI is a tool that enhances, rather than obscures, the creative process. One approach to avoiding the AI Black Box in design is to implement explainable AI (XAI). XAI refers to techniques and methods that make the outputs of AI systems more understandable to humans. This involves creating AI systems that can provide understandable reasons for their decisions or suggestions, allowing designers to make informed choices about whether to follow these suggestions or take a different path. Moreover, as anticipated, avoiding the AI Black Box also involves educating designers about the basics of AI and machine learning. By understanding how AI systems learn, process data, and make decisions, designers can better anticipate and interpret the outputs of these systems. This knowledge is crucial for effectively integrating AI into the design process in a way that is both productive and responsible.

Furthermore, there is a need for continuous monitoring and evaluation of AI systems to ensure that they function as intended and do not inadvertently introduce biases or errors into the design process. Regular audits and updates can help in identifying and correcting any issues that arise, maintaining the integrity and reliability of AI-assisted design processes.

4. Conclusions

The integration of Artificial Intelligence (AI) into the design discipline marks a significant paradigm shift, bringing forth complex challenges and new opportunities. As we delve deeper into this era of digital transformation, the relationship between human creativity and algorithmic processes becomes increasingly intertwined, necessitating continuous study and adaptation.

The evolving dynamics of human-AI interaction in design highlight a transformative shift from traditional, human-centric methodologies to more algorithmically driven practices. This transition is not just about harnessing a new set of tools; it represents a fundamental rethinking of the design process itself. It demands a critical exploration into the ethical management of data, bias mitigation, and decision-making transparency. These aspects are crucial in maintaining the integrity and authenticity of design outputs in an increasingly AI-dominated landscape. It is evident that the technical possibilities offered by computational technologies have consequences beyond the technical area. They intervene in thoughts, approaches, and generation of ideas determining new ways of defining things and their relations. Hence, AI intervenes substantially in the methods and tools to 'make' artifacts, i.e. on the entire design process, raising critical questions about the ways design designs (Giaccardi & Redstrom, 2020).

Moreover, the necessity to continue studying this integration is crucial. As AI technologies evolve, so too must our understanding and methodologies. The field of design must embrace this change, fostering an environment where AI is not seen as a replacement for human creativity but as a collaborator that enhances and expands creative possibilities. This requires a balance, ensuring that AI's computational power is harmonised with human intuition and creativity.

Educational and professional frameworks within the design discipline must evolve to accommodate these changes. This includes integrating AI literacy into design curricula and professional development programs, ensuring that upcoming generations of designers are equipped to navigate this new landscape. Additionally, interdisciplinary collaboration becomes vital, bringing together expertise from fields such as computer science, cognitive psychology, and ethics to address the multifaceted nature of AI in design. Furthermore, the ethical and cultural implications of AI integration in design need continuous scrutiny. As AI systems increasingly influence the creative process, it becomes essential to ensure that these technologies are used responsibly, respecting cultural diversity and social values.

Hence, the journey of integrating AI into design is ongoing and dynamic. It presents a world of possibilities, redefining the essence of creativity and innovation in the design field. However, it also poses significant challenges that must be thoughtfully addressed. In fact, despite the suggestive more-than-human

experiences provided by AI, we are still experimenting with it, often producing risky, concerning, and undesired results (Taddeo & Floridi, 2018). The future of design in the AI era is not just about technological advancement; it's about shaping a future where technology enhances human creativity in ethical, responsible, and culturally sensitive ways.

KEYWORDS | POST-CADASTRAL URBANISM, DIGITAL URBAN CARTOGRAPHIES, REAL-TIME URBAN ANALYTICS, TECHNO-CULTURAL DYNAMICS, ALGORITHMIC URBANISM

ABSTRACT | The contemporary urban landscape delineates a departure from traditional descriptors and historic anchors, propelled by a confluence of pervasive distributed digital systems. The entanglement of the spatial internet, Web3, APIs, digital twins, real-time data, and analogous platform technologies is pivotal, enmeshing, and orchestrating interactions within urban domains. The influence of network technologies ripples across multifaceted dimensions, shaping navigation, mobility, and service provisioning.

Recursive feedback mechanisms and algorithms such as ratings, reviews, suggestions, and recommendations collectively catalyse the attention economy and choice architectures through categorising individual preferences. It is an emergent landscape where the technological infrastructures permeate, not just as tools, but as mediums intertwining with the fabric of societal existence, cultural expression, and urban architecture.

The 'Post-Cadastral' condition establishes and explores a domain of urban and architectural invention – a city's imminent escape from cadastral space, embracing virtual realms and digital ubiquity. It is concerned with the hyper-reality of virtual space as mooring of invisible cultural, economic, and societal forces. The domain of research operates at limits of material and spatial practice, integrating the physical, the virtual and holographic; and engaging with real-time, urban data analytics, simulation, gamification, techno-cultural discourse and narrative, AI, and generative techniques.

The research explores the convergence of augmented urban infrastructures and services, delineating the interwoven threads of value generation (value capture), behavioural shifts, and performance metrics. It unpacks the emergent paradigm where cities, unleashed from historical cartographic constraints, traverse fluid territories shaped by the synergistic forces of digital evaluations and algorithmic orchestration. In this epochal shift, urban spaces transmute into arenas where cadastral limitations yield to an amorphous terrain of digital augmentation and evolving spatial imaginaries.

This paper scrutinizes the intricate interplay of web-centric reviews, ratings, comments, and AI-driven algorithms that organise a departure from conventional urban spatiality – a city abstracted by search terms and contained in the comments sections and sorted by popularity. Delving into this labyrinth, it dissects the convergence of diverse valuation systems, nuanced behavioural patterns, and algorithmically mediated decision-making processes, illuminating the evolving dynamics within contemporary urban environments.

Through projects, bespoke workflows, and methodologies, its objective resides in rendering discernible precise pathways wherein technological transitions become etched within the urban continuum, consequently integrated within the realms of architectural practice.

1. Introduction

The contemporary urban condition and by extension the future proposition for cities is underpinned by elaborate frameworks. Urban landscapes manifest across the boundaries of its instruments and mechanisms. The thresholds between the physical and digital experiences dissolve and architectural sequences intertwine. There is a reverberation brought about by the permeation and inundation of the systems of the city with data and information. This resonance manifests as a chaotic haze, information swirling through the cityscape. Here, the city transcends its mere physicality to embody a dynamic amalgamation of technological, socio-cultural, and political forces, where the amalgamation of data smudges merges seamlessly with the everyday artifacts of human existence.

Embedded within this realm is the essence of the city, extending beyond its tangible structures to encompass the digital fabric interlaced with comment sections, drop-down menus, and the nuanced expressions of approval or aversion evident in reviews, subscriptions, likes, and dislikes. Within this digitized landscape, the urban environment is meticulously organized according to metrics of "relevance" or "popularity," wherein virtual registers methodically decode our behaviours, anticipate our inclinations, and prompt our actions.

The orchestration of daily life, whether within public thoroughfares or private domains, is governed by these virtual entities, guiding individuals through endless feed interfaces, spinning pull-wheels, and incessant scrolling. Algorithms wield significant influence, systematically categorizing the city's amenities and services through recursive processes. However, amid this relentless structuring, the efficacy of the city is not solely defined by its ability to prioritize but also by its capacity to overlook, all under the guise of an architecture of promotional content.

The physical manifestation of the city extends beyond the confines of handheld devices; its infrastructures and amenities intricately interconnect within platform applications and social media platforms, directing behaviour towards predetermined patterns. Within this milieu, the city's potential to facilitate human interaction is scrutinized, as desires are perpetually stimulated, and every manifestation of excess is fervently pursued.

Within this urban ecosystem, the city's devices propagate memes, and its desires seamlessly intertwine with those of its inhabitants, blurring the boundaries between the city's aspirations and individual yearnings.

2. Devices, Instruments, Mechanisms

The subsequent discourse endeavours to dissect and contemplate, both theoretically and concurrently, the interaction between market mechanisms and the instrumental domain of urban architecture, envisaging a tangible practice that is stimulated, calibrated, and sustained by the operations and endeavours of the market.

The city grid serves as a fundamental descriptor of architectural experimentation and consensus. Although the grid was not expressly devised by the market, its patronage ensures that the architectural discourse is influenced by its medium. Market forces and urban architecture exhibit a symbiotic relationship through their logics, patterns, and approximations. Architecture not only occupies property but also serves as an instrument of the property itself, representing a spectrum of specificity encompassing the tools, techniques, and mechanisms employed in realizing objective realities. Urban structures function as relentless agents that delineate and conceptualize the contingent nexus between production and consumption, imparting material, and spatial syntax to formlessness. Architectural devices serve as a language and capability for abstraction to facilitate comprehension.

This confluence between regulation and governance epitomizes architecture as the vessel for socio-political ideals. In the convergence of the market and architecture, abstraction emerges as both a utility and a domain of value. Instruments and mechanisms facilitate the integration of policy and market dynamics within a flexible framework. Architecture embodies the tangible manifestations of both the real and the abstract. The grid, famously described by Rem Koolhaas as the device "that renders the history of architecture and all prior urban lessons irrelevant," (Koolhaas, 1994) not only instigates a novel system of formal values but also provides a rigorous platform and discipline for speculation, both architectural and economic.

Robert Hoddle's Melbourne grid, characterized by minimal allocation of open space, aligns with the maximizing and totalizing influence of market dynamics. Market forces within cities are intertwined with a marketplace of technological instruments, concurrently technical and social in nature. In its current iteration, technology assumes the role of a social institution, with platform technologies and peer-to-peer economies reshaping traditional hierarchical relationships between governing bodies and citizens, disrupting social and civic enterprises.

Architecture's capacity to influence the organization of social activities is inherently connected to its precision in encompassing, accentuating, and imparting precise vocabulary to the organization of economic and market activities. With the advent of distributed technologies, this capacity becomes diffused across a landscape of cumulative individualization, characterized by choice architectures. The current market, shaped by various assemblages and obscurities, emphasizes the contrast between individual and collective elements. Within this construct of connections and activities, the continuum or flow is punctuated by the density and intensity of activities. Devices and apparatuses encapsulate human dispositions, with user data emerging as a commodity in the experience economy, serving as a transactional conduit between the market and the architectural fabric of the city, represented through virtual avatars and physical proxies.

The expansive realm of various technological ecosystems reshapes the dynamics and subtleties of agency, underscoring the asymmetric impact of human dispositions in compelling market actions. The French term "agencement," as expounded by Callon and McFall, underscores the inseparability of agencies and arrangements, encompassing everything from tools and equipment to statements and instructions. (McFall, 2009)

The role of architecture extends beyond mere categorization, rationalization, operationalization, or optimization; rather, it encompasses a fusion of these roles while aspiring to transcend them optimistically. Beneath the surface of marketing strategies lies a deeper inquiry into the potential of architectural mechanisms. Can these mechanisms not only realize inherent potentials but also provoke unforeseen patterns and behaviours beyond their intended purposes? How might architecture push the boundaries of innovation by leveraging keen observations and the nuanced workings of its mechanisms? These questions invite a deeper exploration into the transformative drive of architectural design and its impact on shaping environments and experiences.

3. Cadastral

A cadastre conventionally systematizes the spatial management of land parcels intertwined with supplementary narratives articulating the intricacies of these interests. It extends to include the custodianship or supervision, and often, the appraisal of the parcel and its accompanying enhancements. The establishment of the system sets in motion a sequence of diverse objectives. These objectives encompass fiscal ambitions, including property valuation and taxation. Legal aspirations are also integral, aiming to streamline conveyancing procedures. Furthermore, the system aims to facilitate effective land governance and utilization, especially within planning and administrative frameworks. Additionally, it seeks to nurture sustainable development and environmental stewardship. (International Federation of Surveyors, 2019) A cadastre constitutes a parcel-centric, contemporaneous arrangement of land data, encompassing an exhaustive ledger of vested interests in land, including entitlements, encumbrances, and responsibilities.

At the core of a cadastre is the foundational element of the cadastral plan. Each genesis of a new land parcel necessitates the creation of a fresh cadastral plan, rendering each iteration a snapshot frozen in time. These plans, immutable in their depiction, encapsulate the contours and conditions of the cadastre at the moment of survey. (Intergovernmental Committee on Surveying and Mapping, 2020)

4. Atemporality

The urban landscape is a perpetually shifting entity, a dynamic proscenium where the perception and legibility is recast consecutively. Its essence is not fixed; instead, it undergoes constant constitution and reconstitution. Every moment sees the city's fabric being stretched and moulded by the movement, clashes, logistics, and the myriad operations of its users, stakeholders, and infrastructural networks.

Further accelerating the patterns of perpetual transformation is the subjective concept of 'extreme present'—an abstract, hyperbolized rendition of the 'now'. This extreme present is a juncture where the collective consciousness grapples with an inundation of rapid changes spanning societal structures, data velocity, architectural assemblages, environmental narratives, and the very fabric of reality itself. It exists in the interstices between a past continuously accessed and repurposed, a 'now' disseminated and archived across digital platforms, and futures already set in motion.

Here, time behaves nonlinearly, defying conventional linear trajectories. The extreme present accelerates the possibilities inherent in any given moment, mutating the present into an intense yet elusive state. It defies direct (static) temporal correlations. This particular dynamic of the organization, reaction and expectation of the city, sits in stark contrast to the established frameworks of urban planning and indeed statutory planning or the instruments of the cadastre and surveys.

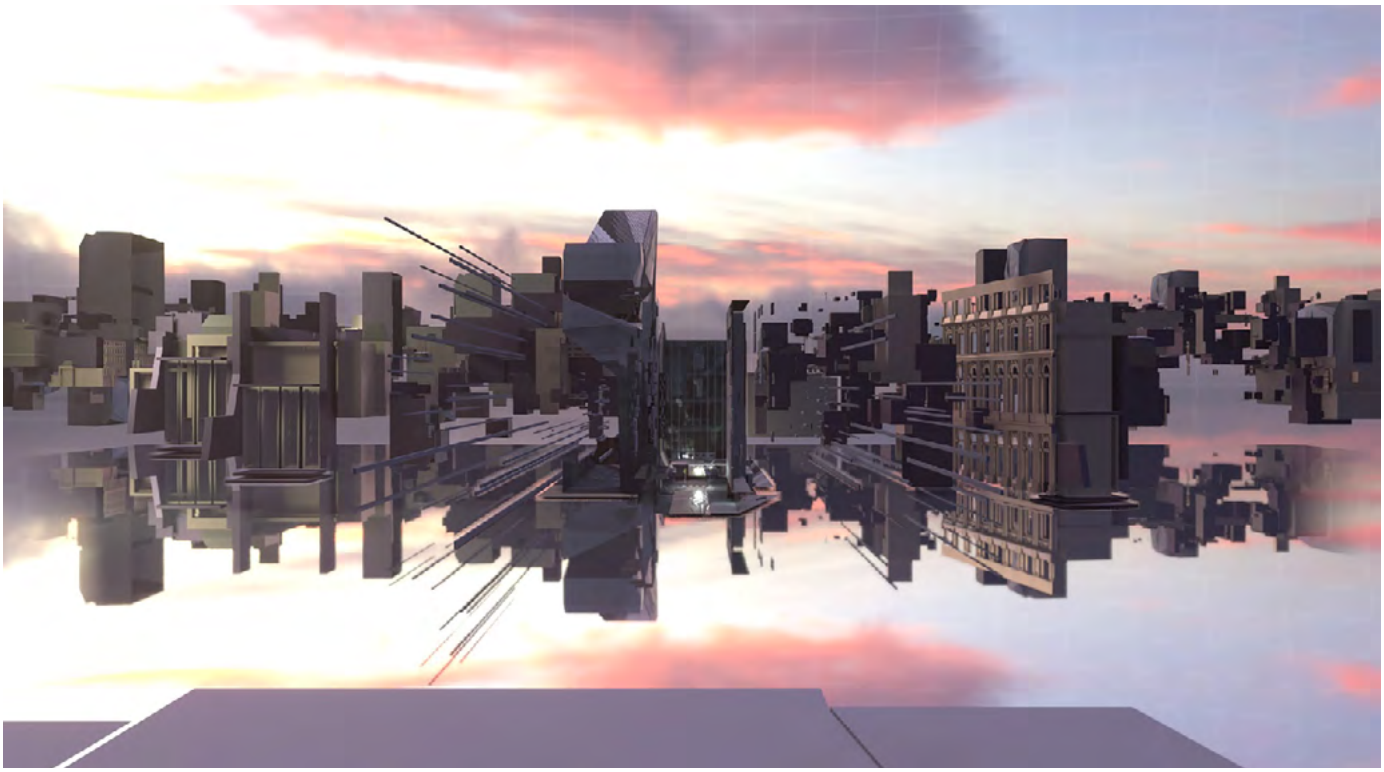

Figure 1. Shapeshifting, transiting between the physical and the virtual, and escaping cadastral space. Image: Kevin Gao with Ian Nazareth and David Schwarzman.

5. Post-Cadastral

The ‘Post-Cadastral’ paradigm speculates about the unfolding of a disruptive dynamic sequence, where cities emancipate themselves from the traditional cartographic and cadastral boundaries. It explores the conceptual terrain of a virtual city, enabled by platform technologies, real time data and digital ubiquity. Of specific interest is the exploration and conceptualisation of the intricacies of these hyper-realities, where the intangible yet potent forces of culture, economy, and society converge within the boundless expanse of virtual space.

Positioned at the edge of material and spatial exploration, the research aims to seamlessly intertwine the tangible with the intangible, bridging the physical, virtual, and holographic dimensions of urban existence. Immersed within this multidimensional framework, the research traverses the fringes of real-time urban data analytics, navigating through the intricate landscapes of simulation, gamification, techno-cultural discourse, artificial intelligence, and generative techniques.

The body of work also engages with a critical examination of the nodes between augmented urban infrastructures and services—a confluence wherein the processes of value generation and capture, behavioural shifts, and performance metrics converge and intertwine. (Nazareth, 2023) Through meticulous dissection, it presents a burgeoning paradigm where cities, unshackled from the confines of historical cartography, embark upon fluid trajectories sculpted by the symbiotic interplay of digital assessments and algorithmic arrangement and orchestration.

In this metamorphosis, urban landscapes cease to be mere static entities confined by cadastral boundaries; instead, they evolve into dynamic arenas pulsating with digital augmentation and evolving spatial imaginaries. As cadastral limitations dissolve, a new paradigm of urban possibility emerges—an amorphous landscape where the boundaries between the physical and the virtual blur, giving rise to a realm of potential and innovation across multi-disciplinary interests and concerns.

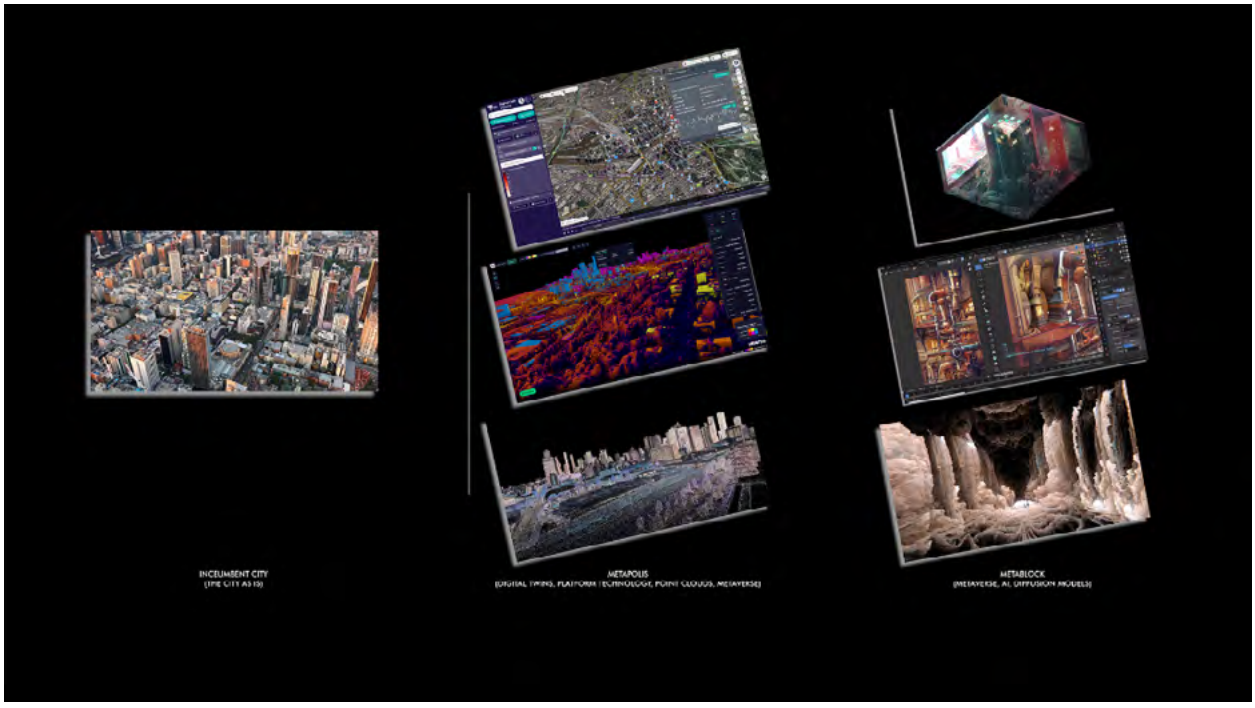

Figure 2. Conceptual platform – (i) the incumbent city (the city as is), (ii) the Metapolis – that connects smart city platform technology, digital twins, real-time analytics, APIs and (iii) the Metablock that builds on the data models of the Metapolis to reconstitute a city block in the open metaverse, spatialized through AI diffusion model and search terms. Image: Ian Nazareth. (The diagram also includes images from HEAVY.AI, NVIDIA Omniverse and City of Melbourne LIDAR Point Cloud Data.)

6. Clayton – Between the Algorithmic Yoke

The subsequent projects are located in Clayton, a suburb 18km southeast of Melbourne CBD, in Australia. Clayton, for purposes of the project is a laboratory for speculations and counterfactual propositions of its urbanism, through harvesting its meta data and locational information. Presently, Clayton is defined as much by the density of exchange as by the relationships between the post-industrial fabric and the suburban intensification projects. It sits within a field of intersections and entanglements - a growth corridor, a major train station, a university and medical precinct, a proposed national innovation and employment cluster – high technology, high science and the suburban rail loop. Here, the nodal will be further intensified by the distributed. (Monash NEIC, 2017) The speculation advances an agenda that the city is not just a multiple of buildings – the city and its metadata determine the valency of a location which is crystallised into a building, or rather, the potential for what a building might be is determined by the city and its virtual presence. It suggests a new extractivisim, appropriation, and contingency and an operative techo-financial space.

In this post-cadastral metropolis, the boundaries between reality and virtuality have long since eroded. The sectoring between government and enterprise has worn thin. As cities yield assets and control, public and private sectors emerge as a techno-political entity of neoliberal machinations. The city is presented as seamless experiences, a holographic luminance, with real-time data streams and strategic capital works projects condensed in geographical and meta space. Here, predictive algorithms dictate the rhythm of the city's life.

The aesthetic, ethical, inter-disciplinary, and philosophical quandaries are not mutually exclusive. The architecture and urban process is one of screened initiative and ingenuity, a rogue subroutine, adapting to the shifting landscapes of behaviour, process and data, actioning and shaping exploits and vulnerabilities.

The urban experience of unfolded encrypted code signals an urban optimisation, of algorithms that parsed the ebb and flow of citizens to maximize efficiency, economic growth, and the seamless propagation of capital. Optimisation is nothing but conformity, meeting the expectations of algorithmic desires and a shallow computation on large datasets.

The city is not homogenous, and the conceptualization of this project seeks to maintain and resist consistency. Between the algorithmic yoke, a city emerges, where the impeding clash of ideologies and generative principles of architecture are dispersed in the data-soaked streets, buildings and infrastructures —the precipice between algorithmic control and the chaotic potential of human experience and rebellion.

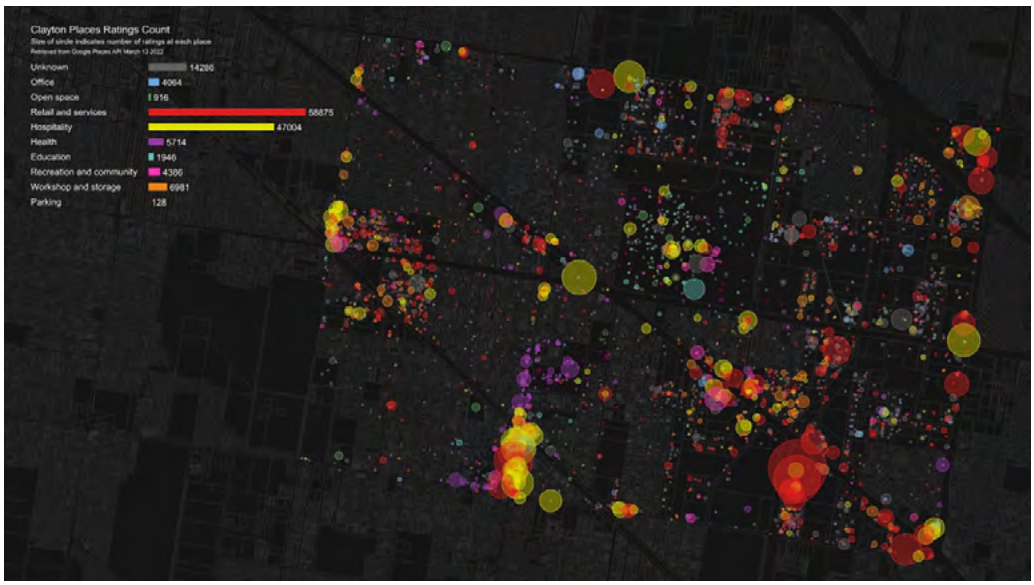

Figure 3. Geolocating user rating counts in Clayton, Melbourne, 2022. Image: Kathryn Larkin and Ian Nazareth.

7. Pattern, Like, User…

The project employs Application Programming Interfaces (APIs), with a specific focus on the Google Places API—a service facilitating the retrieval of information about various locales through HTTP requests. (Nazareth, Schwarzman, 2021) Within this API framework, places are delineated as establishments, geographic coordinates, or important points of interest. Notably, this repository includes user-generated reviews and star ratings, serving as pivotal metrics within a decentralized framework wherein user, customer, and subscriber perspectives converge. These metrics, arguably, represent an open fount of both emotional response and service valuation.

The analysis discerns a correlation between the interpretation, extrapolation, and subsequent manifestation of peaks and troughs within broader processes and mechanisms, particularly within the contexts of real-time data, informational dynamics, and urban development paradigms. Within this framework, the presence of 'noise' within datasets may engender intermittent peaks and troughs, which, over time, assume discernible patterns and forms influencing infrastructural responses, speculative activities, valuations, and urban behavioral patterns. This observation underscores two salient prospects:

1. the potential to access nuanced individual preferences amidst collective dynamics, which exhibit temporal fluctuations; and
2. the propensity for short-term biases and variances within datasets to potentially inform longer-term transformations.

Through the process of data scraping, a diverse array of categorical information is geolocated and spatially represented. The project endeavors to explore potential avenues and mechanisms for integrating this data into the built environment. Assessment, valuation, and categorization of establishments are intricately linked to property and spatial considerations. Hierarchical structures are scrutinized against parameters such as scale, temporal significance, and permanence. API-derived data is meticulously parsed and classified based on aggregated reviews and ratings. Multipliers are employed to amplify the impacts of factors such as popularity, supply, and demand. Consequently, tenancies may expand, contract, or exhibit resistance to change, with instances where the decline of certain establishments surpasses the ascent of others, leading to the emergence of voids within the urban fabric, catalysing a phenomenon of an entrenched hyper-tenancy.

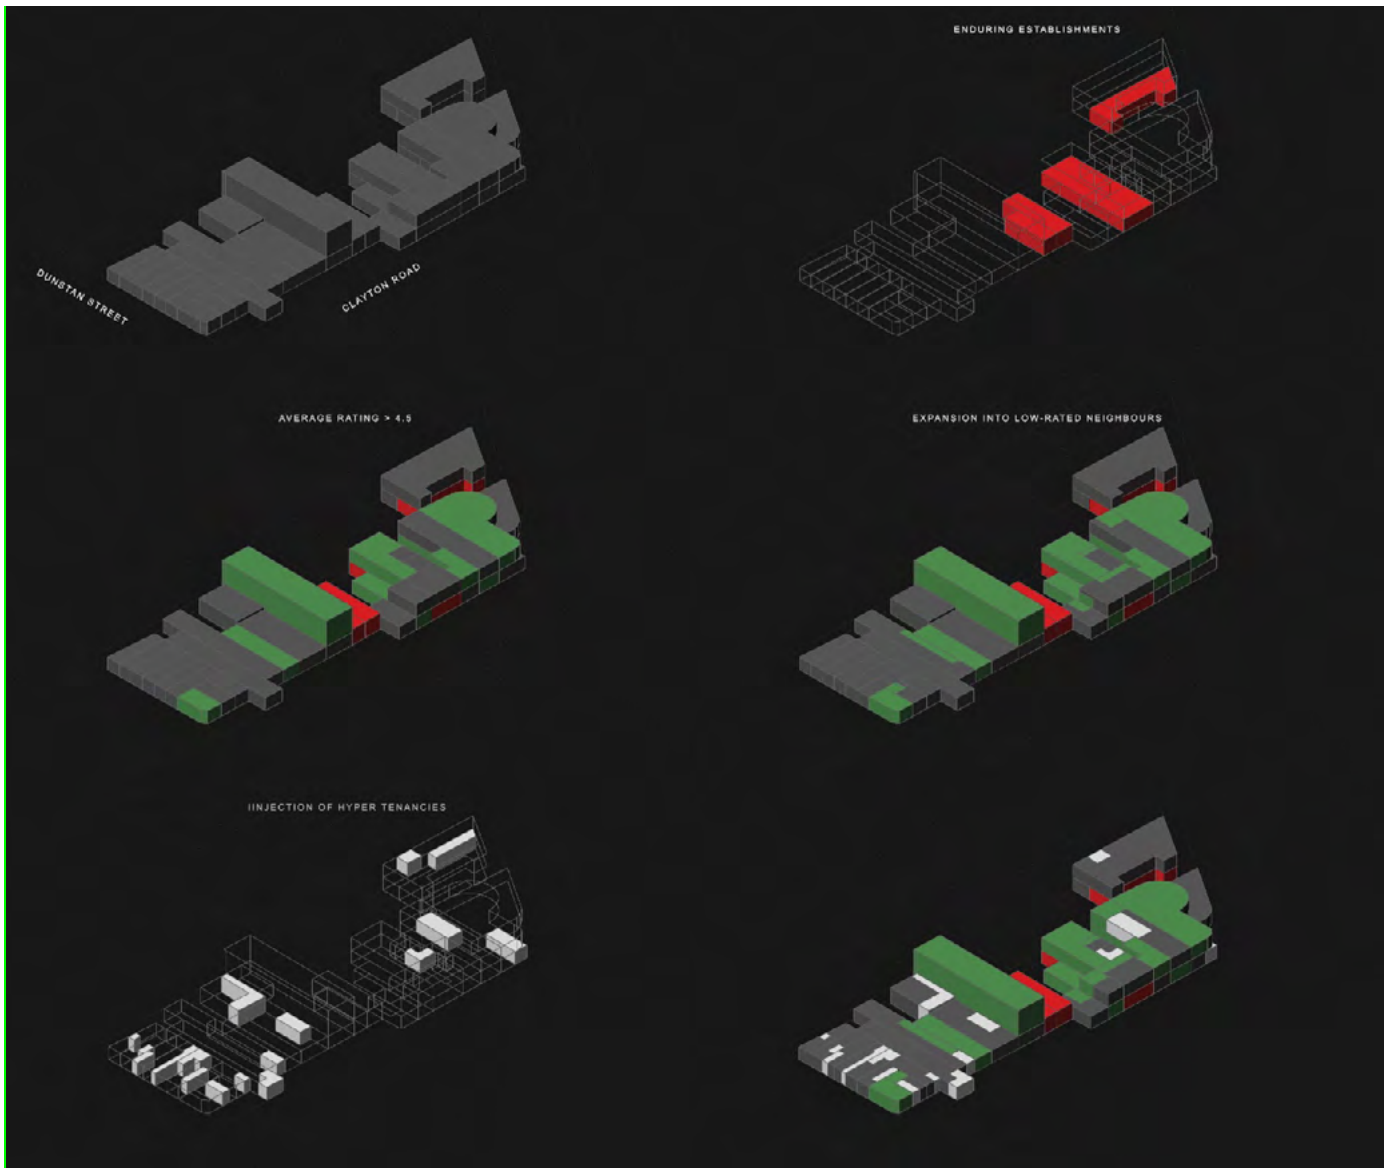

Figure 4. Hyper Tenancies in Clayton, Melbourne, 2022. Image: Kathryn Larkin and Ian Nazareth.

8. Hyper-Tenancies

Individuals play a pivotal role in furnishing platform technology systems with data through various means such as likes, ratings, and reactions. The cumulative effect of these contributions suggests a democratized reservoir of collective detail, information and therefore intelligence. Personal attributes act as a lens through which urban landscapes manifest themselves. Traditional urban hubs, exemplified by the High Street (Main Street), yield precedence to algorithmically curated search results, shaping our personalized encounters with the city.

The concept of hyper-tenancy serves as a deliberate understatement, a distinctive feature within the urban landscape characterized by its service-oriented nature, symbolic resonance, and adaptive deployment. It emerges as a consequence of disruptive forces engendering novel functionalities, mirroring the interplay between digital hype and tangible service capacities. It epitomizes the localization of unbounded expression.

Inflation predicated on popularity represents one facet of this dynamic milieu. It delineates the interactions between consumers, industries, infrastructures, and their urban representations, constituting a public interface. Retail establishments perpetually vie for prominence within the civic realm, paralleled by their

virtual counterparts competing in the digital sphere. The convergence of physical and virtual realms culminates in a distinct urban fabric, intricately interwoven within this realm. Here, the measurement of floor space serves as an indicator of assets and significance, symbolizing value derived through financial, technological, and commercial mechanisms. The inexorable progression towards inevitability is propelled by factors of convenience, initially conceived as an idealistic aspiration but subsequently co-opted by influential power dynamics.

9. The Bi-Lo Hi-Fi

Figure 5. Bi-Lo exterior and car park. Image: Tony Hu and Ian Nazareth.

This project aims to establish a critical and projective design practice. It seeks to engage with urban histories and data, examining the ways in which the city functions through speculative processes. Furthermore, it aims to reposition urban amenity while establishing a paradigm for machines and machine intelligences to inhabit and traverse the urban environment. The project explores various aspects including neuromorphic cartography, urban augmentation, synthetic navigation, and retro-fictive narratives.

Neuromorphic Cartography: Combines principles of neuroscience and cartography to create maps. It uses computational models mimicking neural networks to interpret spatial data, aiming for adaptable mapping systems.

Urban Augmentation: Enhances urban environments through technology like digital infrastructure, IoT devices, extended reality infrastructure and smart systems. The goal is to improve aspects like transportation, sustainability, safety, and efficiency, creating smarter, more connected cities.

Synthetic Navigation: Uses artificial or synthesized data for navigation, including simulated maps, virtual environments, or augmented reality overlays. It's often paired with GPS and computer vision to enhance navigation accuracy, especially in complex areas.

Retro-fictive Narratives: Fictional stories reimagining historical events or past eras from a contemporary

perspective. They blend nostalgia, speculative fiction, and historical revisionism to explore "what if" scenarios or alternate timelines, providing insights into history and memory.

The Bi-Lo Hi-Fi project represents a nuanced exploration and speculative reconstruction of the transition from the Bi-Lo supermarket chain to Coles, epitomized by the emergence of dual Coles supermarkets situated at opposing ends of a desolate car park in Clayton, Melbourne. Within this juxtaposition is a complex narrative of coexistence and spatial advantage. Rebranded as 'Meta-Coles' or 'The Bi-Lo Hi-Fi,' this locale serves as a juncture where relics of the past intersect with contemporary amenities, blurring the boundaries between obsolescence and utility.

Embedded within the network of urban memory and speculative data flows, the 'Bi-Lo Hi-Fi' surfaces as an anomaly, weaving a description through echoes of a counterfactual history. Within the simulation, the urban landscape unfolds as a decipherable cryptogram, with physical artifacts, digital point clouds, real-time data, and Non-Uniform Rational B-Splines Modeling (NURBS) surfaces gradually decoded by human cognition intertwined with the computational insights of machines and AI systems. These overlays unravel the multidimensional codes and augmentations inscribed within the urban fabric.

Through a choreography of esoteric interventions, these structures transcend their commercial origins, evolving into urban relics that straddle the realms of the tangible and intangible. These entities serve as conduits bridging physical reality with the elusive realm of the virtual. They engage in reconceptualizing architectural form, adapting it to accommodate essential services, organizational systems, and non-fungible tokens (NFTs). In doing so, they infuse these elements with fresh subjectivities and value propositions, transforming their significance within the architectural landscape.

The project delves into alternative cartographies, psychogeographies, and narratives of conceptualization, visualization, and immersion within a virtualized urban environment. It envisions a landscape where humans, non-humans, and sophisticated AI systems collaboratively navigate and reinterpret urban spaces. Amidst the flux of corporate dynamics, rebranding endeavours, and market fluctuations within the (extra)urban realm, the project operates within a liminal space, oscillating between corporeal reality and the ethereal expanses of the virtual.

This liminality offers opportunities for novel configurations of amenities, as well as the development of spatial grammar and lexicon comprehensible to both organic and synthetic intelligences within the urban architectural tapestry.

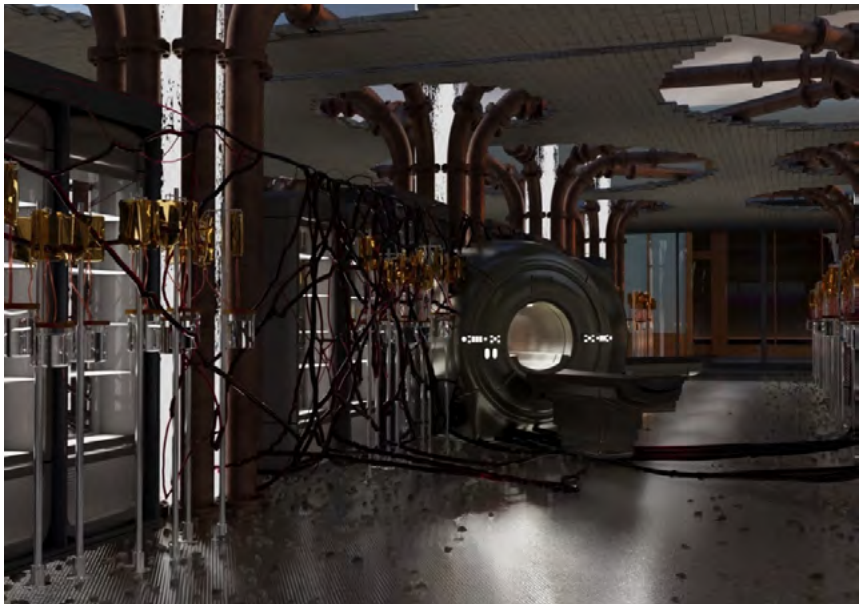

Figure 6. Bi-Lo interior. In its state of obsolescence, it provides a description to accommodate temporal amenity. Image: Tony Hu and Ian Nazareth.

10. Conclusion

In the layered intersections of technological acceleration, economic dynamics, political manoeuvring, and contextual fluctuations, the urban architectural process develops at a pace that seems almost agonizingly slow. Decisions made in the initial stages of long-term strategic urban projects often dictate the fate of major works spanning decades, rendering them obsolete before they even materialize. In this milieu, architecture struggles to capture the zeitgeist, appearing redundant, contemplative, and retrospective.

Meanwhile, the physical infrastructure of cities finds itself increasingly entangled within the realms of technology, as the innocuous internet-of-things, semantic executing web, and Industry 4.0 appropriate urban assets. This fusion accelerates the interaction between static and non-static elements, driving global shifts in topology and characteristics.

We now find ourselves in the midst of gamification, or a gamified urban experience, where gaming mechanics are seamlessly integrated into the fabric of the built environment to encourage participation, offering incentives, risks, and rewards. The city becomes a catalyst for virtual interaction, shaping and reflecting human impulses in a stochastic, non-deterministic manner.

The post-cadastral state engages in a nuanced negotiation between liberating and constraining the physical infrastructure of the urban environment, catalyzing temporal dynamics and potentials towards acceleration and exponential growth (Kurzweil, 2001). Within this theoretical framework, the perception of choice becomes entwined with structures of preference, fostering a cumulative effect through innovative combinations.

This proposition operates within the realm of speculation, persistently navigating the boundaries delineating rationality and speculative thought. It adeptly manoeuvres through esoteric realms, embraces idiosyncrasies, and penetrates pervasive constructs, addressing the turbulent techno-political climate and the stark contrast between claims of reality and simulation. Employing unconventional methodologies, it disrupts the delicate balance within urban and architectural discourses, grappling with an alternative urban narrative.

The conceptually flexible domain of the Post-Cadastral condition provides a means to abstractly represent the city, to reveal its full potential by reordering data and facts into landscapes of relevance. This city of the future harnesses spatio-temporal models to create functional representations that extend far beyond the limitations of current urbanity, sensing and adapting to its environment on a scale previously unimaginable. It becomes not just a settlement pattern, but a technology itself—an infinite canvas of spatial and temporal possibilities.

As new and systemic complexities continue to challenge our societal structures, the role of design in shaping and influencing spaces of governance, business, and innovation is becoming increasingly vital. Global challenges demand innovative approaches, and design, with its capacity to navigate and reframe these complexities, holds the potential to play a transformative role. This track explored the narratives of governmental policy design and the emergence of alternative economic frameworks. As governments struggle with new economic realities and businesses seek to innovate within shifting markets, design offers a unique toolkit for addressing these challenges.

The track was also a reflection on the evolving boundaries of today's creative industry, encompassing everything from corporate design initiatives to entrepreneurial ventures.

Our authors clearly stated that strategic, design-driven decision-making must play a more central role in shaping our collective future. For this to occur, it is essential to develop new, frameworks for evaluating design's impact. How can designers effectively influence business and policy decisions? Can we measure the tangible and intangible impacts of design? What methods and approaches are effective, and which fall short? Given the inherent agency in design, this discourse aims to address the evolving position of design in contemporary contexts, emphasizing its critical role in shaping the future of governance, business, and innovation. These topics are crucial, as they highlight design's growing responsibility in shaping the systems and structures that define our world.

While the track prescribed an approach focused on the systemic and strategic dimension of design, authors could choose the purpose to which such an approach is applied.

One area of focus was sustainability, which is an overarching issue that characterises much of the innovation efforts of the past decade across many disciplines.

Design is a profession responsible for defining desirable products (and services) and hence it is capable of promoting consumption, a reason why it has been criticised in the past from a sustainability perspective, but that is also why Design Research tackles mitigating negative impacts, as well as building design capabilities focused on environmental sustainability.

On the most immediate level, these capabilities can be focused on the threefold principles of "reduce reuse recycle", exploring the necessary design approaches to optimise material use, adequate production technologies, as well as consumer behaviour changes that lead to longer product lifespans or more sustainable purchase choices.

However, design can tackle sustainability also at the level of organisations, from interventions in existing companies to setting up new enterprises, up until shifting values in an entire market segment.
The four contributions in the "Designing for Sustainable Economies" session focused on integrating design principles with environmental sustainability in product design, circular economies, and premium markets.

Sustainable design practices can be challenging to implement in well-established enterprises with industrially relevant production and tight profit margins, and one of the contributions tackled these by analysing the practical challenges both based on a semi-systematic literature review and an interview campaign.

A fundamentally different approach was represented by an entrepreneurial project from the Amazon rainforest, experimenting with bioeconomy based on growing useful design objects on trees and, in particular, establishing a local community of artisans to manage production.
Another contribution argued that, conversely, shifting the high-end market might stimulate the diffusion of good sustainable design practices.

Finally, a critical reflection highlighted the potential oxymoron lying behind the term circular economy, proposing that there is a need for a regenerative economy, which requires not only a regenerative design approach, but also systemic policy changes in order to adapt to the Anthropocene.

Another group of contributions in the track, arranged in the "Local Design Strategies" session, have explored how design can act strategically to develop projects that are relevant to a specific geographic area.

The first one in this session focused on how to prepare the interdisciplinary students of a Master in Business Design for an entrepreneurial role, developing their skills at the "Entrepreneurship Through Design" workshop, which also allowed them to critically assess the effort distribution throughout the innovation process, confronting the double diamond model with its practice.

The other two contributions in this session reflected on the design strategies within a manufacturing company and a territorial system of manufacturers.

In enterprises, Chief Design Officers (CDO) have an increasing presence, but their position and roles are still not entirely well understood, therefore one of the presented papers has observed and analysed the CDO's activities in a company, highlighting its mediator role between various organisational units and disciplinary backgrounds.

On the other hand, the success of design products often depends on the effectiveness of an entire industrial district, rather than a single manufacturer's capabilities. The second contribution argues that beyond effective

supply chain management, for sustainable development it is essential to establish a “cultural value chain”, which considers local identity and community, thus leveraging and further enhancing cultural capital.

Finally, the session named “Perspectives of Innovation” examined design methodologies and cultural entrepreneurship, exploring new methods to foster innovation and deliver value. Design Thinking received some criticism recently, however, its influence remains and continues to impact how businesses operate. While its benefits are known, its role in promoting ambidexterity is less studied.

One paper presented case studies, identified key factors for successful Design Thinking implementation and its impact on organizational learning, particularly valuable for managers. Another contributor went beyond this methodology and explored how sensemaking and effectual thinking can enhance normative design thinking, presenting design as an imaginative, embodied practice that evolves through stakeholder collaboration, reflection, and learning.

The importance of a design-based approach, using design as a steering force in urban innovation processes was explored in another case study. Often overshadowed by administrative concerns, here, design’s value was demonstrated even in the procurement process.

To make sure, the track covered multiple dimensions of the market, it featured papers demonstrating design’s influence beyond corporations. A study explored crowdfunding’s potential at micro, meso, and macro levels, highlighting its role in innovation, and economic growth, especially for small- and medium-sized enterprises in light of recent regulatory changes.

Leaving the business world behind, one of our contributors presented a case for public services. In this scenario, the digital transformation of the public sector fostered collaboration and experimentation, making room for design practices such as design thinking and service design. The paper explored how the Design Research Lab (DRL) framework, rooted in the arts, and focused on public interest, can offer valuable insights for improving public sector innovation labs.

As track chairs, looking back at our track, we observed that case studies showcasing the relationship between design and the economy are highly important for Cumulus. This should be treated as a key topic, as design in the business world tries to assert itself within capitalism, in the face of numerous other dominant approaches.

KEYWORDS | PREMIUM DESIGN, DESIGN FOR SUSTAINABILITY, DESIGN STRATEGIES

ABSTRACT | The sustainability challenge is one of the most pressing issues facing our world today, encompassing various environmental, social, and economic concerns. Addressing sustainability complexities necessitates a profound and radical transformation of our development model. This transformation involves not only production processes but also patterns of consumption and access to goods and services (United Nations, 2023). Design has emerged as a powerful tool to address these sustainability challenges (Walker, 2006; Bhamra & Lofthouse, 2007). Pioneering this integration of design and environment in 1985, Victor Papanek introduced profound environmental considerations into the design realm (Papanek, 1985). Building upon Papanek's legacy, the evolution of design for sustainability unfolded gradually from the early 1990s to the contemporary era, marked by diverse approaches and frameworks across different scopes and scales of innovation. In 2016, Adams et al. revealed a transformative shift from a narrow technical and product-centric orientation to an emphasis on system-level changes, addressing sustainability as a challenge to be tackled at a socio-technical-ecological system level (Ceschin & Gaziuluoy, 2020).

Confronted with an imperative challenge that demands immediate attention, the high-end market landscape is progressively under pressure and intensifying in its competitiveness. How to create new values in line with contemporary consumers and bring meaningful changes through design with a premium push to attain a long-term sustainable impact has emerged as a crucial subject for leading companies and organizations (Hemmings, 2019). The premium design encapsulates superior material quality, functional efficacy, and aesthetic allure into the fabric of products and services, thereby augmenting their perceived value and desirability within the high-end domain. It requires a delicate balance between shared value and banalization, ensuring quality preservation in the availability of products and services to a broader audience without diluting their fundamental essence (Ingaramo, 2022). This approach can mitigate irrational economic and environmental impacts through resource optimization while enhancing product quality and service efficiency. It resonates with consumers who value quality and ethical, environmentally conscious lifestyles and promotes the market's transition towards sustainable practices.

This paper employs a combined methodology, comprising a literature review and case studies, to elucidate the intricate interaction of the premium design approach across multiple design for sustainability levels. It aims to investigate the potential perspectives of such an approach in embedding sustainable values in the high-end market, ranging from product to service and social system spheres. The authors wish to offer valuable insights that can be used as a reference by fellow researchers engaged in exploring sustainability-focused design across relevant domains.

1. Introduction

The sustainability challenge is one of the most pressing issues facing our world today, encompassing various environmental, social, and economic concerns. Despite the declaration of a "code red for humanity" (United Nations, 2021) in the climate emergency, the prevailing trajectory diverges from the critical objective of limiting global warming to 1.5 degrees, posing a risk of exceeding 3 degrees by 2100 (COP26, 2021). While some progress is evident, an urgent call for decisive action to curb global temperature increases to the vital 1.5-degree threshold persists. A paradigm shift is imperative, emphasizing the transition from mere commitments to immediate, tangible actions, aligning economies with the natural world for a sustainable future. Effectively addressing the complexities of sustainability demands a profound and radical transformation of our development model, impacting production processes, consumption patterns, and access to goods and services. "We cannot simply continue with more of the same and expect a different result" (United Nations, 2023, p. 4). As emphasized by O'Brien, achieving comprehensive climate action requires a multifaceted transformation. Beyond technical and behavioral adjustments, a compelling need exists to reconfigure political structures, reshape belief systems, evolve values, and reconsider worldviews and personal behaviors (2018).

Confronted with an imperative challenge that demands immediate attention and action, the high-end market landscape is progressively under pressure and intensifying in its competitiveness. Most major advertisers have committed to achieving net zero by 2050, if not sooner. This commitment is mirrored globally among many leading brands, who have undertaken the pledge to achieve net-zero targets by 2050 or even sooner. Notably, a significant shift in climate action is observable within the Fortune Global 500. Thirty percent of these influential companies have either successfully achieved or publicly committed to ambitious climate goals by 2030, signifying a substantial rise from the relatively meager 6 percent reported in 2016 (Lu, 2021). In today's dynamic business environment, brands are actively steering away from "greenwashing" while guiding their consumers in transforming sustainable intentions into concrete action through impactful, transparent, and positive messaging. Creating new values aligned with contemporary consumers and bringing meaningful changes to attain a long-term sustainable impact has become crucial for leading companies and organizations (Hemmings, 2019). Design, in the current landscape, has emerged as a potent tool in facilitating and driving such transformation (Walker, 2006; Bhamra & Lofthouse, 2007).

2. The Essence of Sustainable Design

Pioneering this integration of design and environment in 1985, Victor Papanek introduced profound environmental considerations into the design realm (Papanek, 1985). He critiqued the consumer-driven nature of design, challenging the prevailing consumerist culture and calling for a more mindful and responsible approach to creating products. In line with the title of his book "Design for the Real World," Papanek underscored designers' social and environmental responsibility, urging them to be agents of positive change, advocating for social and environmental justice through their work and emphasizing meeting the real needs of social communities. Building upon Papanek's legacy, the evolution of design for sustainability unfolded gradually from the early 1990s to the contemporary era, marked by diverse approaches and frameworks across different scopes and scales of innovation. A study by Adams et al. found that the literature surrounding sustainable innovation has traditionally centered on technical solutions and gradual adjustments. However, recent perspectives highlight a shift towards people-centered innovation, viewing sustainability as a socio-technical challenge. Early emphasis on technical responses has evolved into a more comprehensive and systemic understanding, extending to a broader socio-economic system. Leading entities in this field now embrace novel business models and services with technological solutions (Adams et al., 2016). Building upon such insights, Ceschin and Gaziuluoy have expanded the design for sustainability framework by introducing an advanced innovation level. This elevated perspective envisions an earth-centric approach that comprehensively integrates socio-technical-ecological systems. Emphasizing a holistic view directs attention towards ongoing transitions, reflecting a forward-thinking stance in pursuing sustainable design (Ceschin & Gaziuluoy, 2020). As we progress into the upcoming

decades and witness the establishment of new dynamic equilibriums, another question emerges: What will define the essence of sustainable design in these post-transition contexts. Sametinger suggests that such essence may lie in interdisciplinary knowledge, the ability to transcend boundaries, and intrinsic motivation for ethical design practices, moving towards a "post-sustainable" (Sametinger, 2019, p. 41) design perspective: "sustainability by default" (Ibid.), which signifies that the fundamental values and principles of sustainability are seamlessly integrated into the design, constituting an inherent aspect rather than an additive element in the design process.

Defaults, in this context, encompass pre-established options individuals encounter, either predetermined or automatically assigned. Faced with these default choices, individuals often accept them without actively exploring alternatives (Smith et al., 2013). In behavioral science and marketing, default settings are potent tools to influence human behavior and capture a broader market share (Thaler & Sunstein, 2008). Within the design domain, practitioners and researchers are responsible for adeptly incorporating and standardizing this influential tool. This involves integrating sustainable values and principles into the design process "without awareness," streamlining the decision-making process for consumers to choose sustainability and facilitating the adoption of sustainable lifestyles.

In the premium market and beyond, promoting sustainability as the default and superior choice for consumers is termed "eco-accidentalism" (Holmes, 2022). This concept involves inadvertently encouraging environmentally conscious decisions, making sustainable options the default and the best selections in various marketplaces. The emergence of the notion is rooted in many research findings revealing a pronounced disparity between consumers' professed intentions and their actual spending behavior (IBV, 2022). Despite over half of consumers expressing a willingness to pay a premium for environmentally responsible brands (Orrell et al., 2021), a significant gap exists between their stated preferences and purchasing actions. To mitigate such a gap and fulfill unmet consumer needs, strategic initiatives must be directed toward overcoming obstacles throughout the consumer journey. By augmenting the accessibility of sustainable options while upholding product quality standards and facilitating a smoother transition for consumers, companies would have the potential to harmonize and influence consumer preferences, and consequently address environmental concerns and align with consumer demands within the market. This explains why the strategy of "eco-accidentalism" comes to the forefront as a potentially practical solution (WARC, 2022).

3. Premium Design: An Eco-Accidental Approach

The design discipline has undergone extensive exploration, evolving from its initial focus on endowing tangible objects with value to encompassing services and, more contemporarily, entire lifestyles (Celaschi, 2000). Design, in essence, involves imbuing products with material, functional, and aesthetic qualities, fostering a connection between form, functionality, materials, and surfaces. Throughout its evolution, these design elements have transitioned from mere characteristics to potent tools for enhancing the perceived value of goods and overall user experience within the marketplace. This evolution has intricately linked design with notions of high quality and luxury, which extends beyond the economic realm, forming a systemic landscape of values that attract, influence, and fulfil human needs, giving rise to a widely recognized premium paradigm (Volli, 2012; Harman, 2018).

In the contemporary landscape, the accessibility of high-end products and services has undergone a profound shift, evolving into a spontaneous, attainable experience by dismantling entry barriers. This evolution extends the potential for luxury to the middle class and the newly wealthy, less tethered to economic status but more to customer satisfaction (Bain & Company, 2021). The democratization of high-end markets signals a fading social stratification, granting everyone access to luxurious and exclusive experiences (Kapferer & Bastien, 2012). The concept of "premium" seamlessly aligns with this transformative narrative. Rooted in the Latin word "praemium," denoting prize or reward, the term "premium" draws connections to attractiveness, ambition, and peer competition, where rewards are consequential to individual efforts and choices. Within the premium paradigm, the economic value represents only one aspect; the further importance lies in the acknowledgment

that extends from material to societal value transformations, which guides consumers to (un)consciously select and enrich a multi-dimensional user experience (Teil, cited in Kapferer and Bastien, 2012, p. 79).

In today's voracious and redundant consumerist society, values once deemed distant from high-end products are now recognized as distinctive imperatives. They play a pivotal role in enhancing and imbuing positivity into the overall consumer experience and utilizing products and services. Leading organizations and companies are currently emphasizing novel values to attract and retain a fresh wave of consumers. In this evolving context, premium design is ideal for elevating the consumer experience and integrating with this transformative reality. The premium design encapsulates superior material quality, functional efficacy, detail sophistication, and aesthetic allure, enriching products and services' perceived value and desirability in the high-end domain. It requires a delicate balance between shared value and banalization, ensuring that products and services maintain their quality even as they become accessible to a broader audience without compromising their fundamental essence (Ingaramo, 2022). Such an approach optimizes resources, mitigates irrational economic and environmental impacts, and encourages socio-technical innovation to enhance product quality and service efficiency. Nowadays, consumers anticipate and actively seek out this formula, which can resonate particularly well with those who value quality, ethical practices, and environmentally conscious lifestyles, fostering a market transition towards sustainability. The following sections present four case studies to explain this concept better.

3.1 Orange Fiber: An Innovative Citrus-Based Fabric

Orange Fiber is a Sicilian company founded in 2014. Since its inception, it has been driven by a mission to actively contribute to an environmentally friendly future for the textile industry. The story of this start-up of two young Sicilian women started with the idea of utilizing "pastazzo," the residue remaining after citrus juice production, which constitutes a substantial 60 percent of the fresh fruit's weight, to create a sustainable and vitamin-rich fabric. Their groundbreaking journey began in 2012 when, in collaboration with the Politecnico di Milano, they developed an innovative process capable of transforming over 700,000 tons of waste generated annually by Italy's citrus processing industry into high-quality fabric. Unlike current artificial cellulosic fibers, this solution significantly curtails the exploitation of land and water, along with the usage of environmentally harmful pesticides (Caruso, 2014). Commencing in Sicily, cellulose is extracted from citrus pulp, marking the initial step. Subsequently, the extracted cellulose embarks on a journey to Spain, where a strategic partner transforms it into yarn. The journey comes full circle as the processed yarn returns to Italy, specifically to a Como weaving mill. Here, it undergoes the final transformation into a luxurious and sustainable fabric tailored for the fashion-luxury sector (Blueislands, 2017).

Throughout the years, their transformative and sustainable initiatives have earned them numerous awards, demonstrating that innovative thinking, collaboration, and a dedication to sustainable practices can not only align with industry demands but also foster a positive global sustainable impact. Orange Fiber, patented in Italy in 2013, took a significant stride by registering its trademark the following year—a pivotal move in discerning products featuring their exclusive yarns and fabrics. With dedicated labels, end consumers can effortlessly identify garments and furnishings crafted from Orange Fiber's citrus fabrics, showing the brands committed to their innovative and sustainable materials (Ibid.).

In 2017, Salvatore Ferragamo launched a capsule collection in collaboration with Orange Fiber on the 47th Earth Day (Figure 1). Made in Italy, luxury fashion, premium design, and sustainable practice—all these elements are encompassed in this "Responsible Passion" project (Giannetto, 2017). The impeccable quality of Orange Fiber mirrors the luxurious appearance and tactile elegance of silk, the exquisite prints crafted by Italian designer Mario Trimarchi, and the distinctive style synonymous with the Salvatore Ferragamo Maison converge to create an exclusive collection reminiscent of a poetic ode to the Mediterranean lifestyle (Ferragamo, 2017). Orange Fiber's commitment to transforming waste products destined for disposal into sustainable and enchanting fabrics showcases a remarkable blend of innovation, environmental responsibility, and community engagement. The company's journey exemplifies how creative solutions and strategic partnerships can contribute to a more sustainable and circular future for the textile industry.

Figure 1. Ferragamo Orange Fiber Collection S/S 2017. Source: mariotrimarchi.design.

3.2 La Compagnie: An Exclusive All-Business-Class Airline

La Compagnie, a distinguished French boutique airline founded in 2013, is dedicated to revolutionizing business aviation. Operating as an exclusive all-business-class airline, it provides flights to New York from Paris, Nice, and Milan, aiming to redefine business class with a personalized travel experience at an affordable rate. In contrast to conventional aircraft with a seating capacity of 230 seats, La Compagnie's Airbus A321neo features a spacious 2-2 layout accommodating only 76 seats (Figure 2). This design prioritizes passenger comfort, offering fully reclining seats that transform into horizontal beds measuring 192cm in length, complemented by a luxurious, thick overlay. The Airbus A321neo distinguishes itself as an efficient, quieter, and environmentally sustainable aircraft, boasting a remarkable 30 percent reduction in fuel consumption compared to its predecessors, emitting a carbon footprint that is 20 to 30 percent lower than competitors flying similar routes (BARR, 2023). Additionally, La Compagnie's ticket prices are approximately 30 to 50 percent more economical than the business class offerings of other carriers, changeable tickets at no extra cost (Ibid.). In 2022, the airline achieved an average load factor of about 75 percent, reaching 80 percent during the summer peak. The seasonal route from Nice to New York excelled with an impressive 85 percent load factor (AirGuide, 2023). These robust load factors instill confidence in La Compagnie for future growth and the launch of new routes.

Regarding the demographics of travelers, the airline reports a well-balanced mix of American leisure and European business travelers. Designed for stress-free journeys, the entire travel experience encompasses expedited airport departures through time-saving fast tracks, creating a seamless transition to the onboard ambiance and in-flight atmosphere. Safety instructions are creatively delivered through an emotional yoga-style video, and each seat is furnished with an extra-large 15.6-inch screen display. The fast satellite unlimited wifi connection ensures uninterrupted streaming. The specialized “bistronomic” cuisine offers extensive special request meal options prioritizing passengers’ health. Every tiny detail contributes to creating a comfortable and smart journey, ensuring the “Relax Onboard” experience (La Compagnie, 2023, p. 15)

La Compagnie’s business model thrives on a flexible and premiumised structure, utilizing modern and efficient aircraft to capture business clientele and a substantial portion of the leisure market. Christian Vernet, CEO of La Compagnie, underscores their services’ uniqueness and special nature, coupled with fare

flexibility, catering to a diverse audience that extends beyond business to include leisure travelers. Their focus on the "creative class," encompassing individuals in startups, design, fashion, art, and the broader lifestyle realm, sets them apart. Vernet emphasizes the privileged perspective they have on this creative class. La Compagnie's offerings are complemented by an optimal timetable, maximizing arrival and departure times, which is especially beneficial for business travelers. In essence, the airline distinguishes itself from competitors by providing superior travel comfort and user-friendly experiences. Vernet characterizes La Compagnie as a "Smart Business," highlighting their competitiveness in terms of costs and agility, a significant advantage over rivals in the business class travel sector (Incorvati, 2023).

Figure 2. La Compagnie's Relax Onboard experience. Source: lacompagnie.com.

3.3 NEXT: A Future Smart Transportation System

Established in 2017, NEXT Future Transportation stands as a pioneering Italian startup on a mission to revolutionize the field of road transport (Figure 3). The seeds of its groundbreaking concept were sown in 2012 by Tommaso Gecchelin, the visionary designer and founder of NEXT. He envisioned a prototype of self-driving vehicles for public transportation, with the audacious goal of seamlessly blending the convenience and sustainability inherent in buses with the nimble flexibility characteristic of taxis. The journey from conceptualization to realization gained momentum in 2015 when Tommaso Gecchelin found a crucial ally in Silicon Valley, the company's co-founder Emmanuele Spera. Their collaboration catalyzed the ambitious vision into a tangible and transformative project (Perfetto, 2015). Together, they embarked on a mission to redefine the future of transportation, combining innovative design and cutting-edge technology to create a dynamic and sustainable solution for the evolving urban mobility needs.

NEXT has ingeniously engineered a modular bus equipped with electric modules that seamlessly connect and disconnect as needed. This cutting-edge design enables the bus to operate autonomously without a driver, ensuring total security and compliance with permissible areas. The hallmark of this innovation lies in the dynamic modularity, allowing these modules to seamlessly connect and detach on standard urban roads, creating an open corridor when joined. Passengers benefit from the freedom to stand and move effortlessly between modules. These modules follow a shared route before detaching based on passengers' selected destinations, facilitated through a dedicated app (Gecchelin, 2023). The dynamic modularity ensures omnipresence and adaptability, akin to a personal car. Each vehicle can comfortably accommodate up to 10 passengers (six seated, four standing), measuring two and a half meters. Crafted

with a blend of lightweight yet durable aluminum, featuring four steering wheels, and powered by electricity, these buses provide enhanced coverage in geographically dispersed areas, elevating the overall level of comfort (Mazzucco, 2020).

In forward-thinking cities like Dubai, the concept of modularity introduces a paradigm of on-the-move transshipment. This dynamic approach optimizes system capacity, resulting in a substantial reduction of over 60 percent in fuel consumption, operating costs, and traffic congestion. Simultaneously, it enhances capillarity and passenger comfort, emulating an advanced on-demand shared taxi system free of intermediate stops and waiting times (Maci, 2020). The versatility of NEXT extends beyond sophisticated urban settings to simpler and easily implementable scenarios, such as the "variable capacity bus" concept. In this scenario, the bus driver dynamically adjusts the number of docked modules for traditionally scheduled services based on real-time data from NEXT. Even without autonomous driving and multiple drivers, this adaptive supply-to-demand approach ensures significant energy and maintenance cost savings, surpassing 50 percent (Gecchelin, 2023).

NEXT envisions a paradigm shift in the field of transportation, elevating it beyond a mere utility to become a living embodiment of "life in motion." NEXT's adaptability and transformative potential extend beyond conventional transportation, permeating domains such as retail and on-the-move services, healthcare, security, cargo transport, and airport services (Ibid.). More than just a mode of transport, NEXT represents a comprehensive solution. Its premium design and forward-thinking approach position NEXT as a catalyst for reshaping how we perceive and experience the journey, transcending traditional boundaries, and ushering in a new era of vibrant and seamlessly integrated mobility solutions.

Figure 3. NEXT modular, sustainable transportation solution. Source: (up) topsimages.com (down) aisociety-unipd.it.

3.4 The Line: A Revolutionary Vertical City

Nestled within the visionary Neom project in Saudi Arabia, The Line emerges as a groundbreaking linear smart city, stretching 170 kilometers across captivating landscapes, from the majestic mountains of NEOM to the enchanting Red Sea (Figure 4). This revolutionary urban development, a pivotal part of the Saudi Vision 2030 initiative, is designed with a singular purpose – to redefine the very essence of cities and urban living. Unlike traditional cities, The Line boldly discards the conventional concepts of roads, cars, and emissions. It is a cognitive city, standing as a mirrored architectural masterpiece soaring 500 meters above sea level, yet ingeniously compact with a land-saving width of only 200 meters. Its innovative design ensures a harmonious coexistence with nature, dedicating 95 percent of the land to preservation while operating entirely on 100 percent renewable solar, wind, and hydrogen energy. Excavation work, initiated along the entire length of the project by October 2022, signifies the ambitious vision of creating a city prioritizing the health and well-being of its residents over traditional transportation and infrastructure

concerns. The Line's blueprint envisions a utopian population of 9 million, comprising 25 percent of Saudi Arabia's current populace. The Line's reduced infrastructure footprint, spanning a mere 34 square kilometers, promises unparalleled efficiencies in city functions. This forward-thinking city ensures residents' convenience with daily essentials accessible within a five-minute walk and a high-speed rail facilitating an end-to-end transit time of just 20 minutes.

The ideal climate throughout the year further enhances the residents' experience, allowing them to blend with the surrounding nature seamlessly. As a pivotal component of the larger $500 billion Neom project, The Line embodies the principles of sustainable urban development, stands as a testament to the transformative power of innovation, and underscores a bold vision for future cities (NEOM, 2022).

The Line introduces a revolutionary urban design paradigm, embodying the concept of zero-gravity urbanism, which means minimizing reliance on the natural ground plane by establishing multiple vertically organized ground planes at elevated heights (Barandy, 2022). Unlike conventional tall buildings, The Line's innovative approach abandons the classification idea of zones and lays various city functions vertically, integrating living, working, studying, and entertaining synergetically. Residents can effortlessly navigate in three dimensions—up, down, or across—to access all their daily needs within a convenient five-minute radius. This innovative morphology ensures equal access to public services and amenities for residents from all backgrounds, allowing them to choose living preferences either vertically or along its length based on personal preference (Ibid.).

This forward-thinking cityscape features an outer mirror facade that not only allows for captivating views and natural sunlight but also bestows a unique identity, seamlessly merging with nature despite its compact size. The Line's groundbreaking blueprint disrupts conventional urban design by fully digitizing the city's plans and embracing significant industrialization in construction processes. This entails pioneering advancements in construction technologies and manufacturing methods, signaling a departure from the norm. While facing criticism for deviating from traditional urban design and concerns regarding sustainability and feasibility, the realization of The Line holds the potential to revolutionize our way of life, echoing the words of Mohammed bin Salman, Crown Prince of Saudi Arabia and Chairman of the NEOM Board of Directors, who envisions, "The Line will tackle humanity's challenges in urban life today and will shine a light on alternative ways to live" (NEOM, 2022).

4. Discussion and Reflection

Premium design emerges as a potent tool for driving sustainable practices, leveraging the historical evolution of design elements from the refinement of tangible objects to the shaping of entire lifestyles. Beyond mere economic value, the democratization of high-end markets becomes a compelling narrative, echoing societal shifts and aligning with the dynamic values of discerning consumers. Analyzing the four case studies described above provides more precise insights into its potential to embed sustainable values within the high-end market.

Rooted in circular economy practices, where waste transforms into high-quality products, exemplified by Orange Fiber, the premium design approach helps transform an environmental challenge that navigates beyond material innovation into a luxurious and innovative solution, ensuring exclusivity and desirability. In the case of La Compagnie, adopting this approach not only harmonizes opulence with ecological mindfulness but also democratizes sustainable luxury, presenting distinctive and responsible value propositions to consumers who, consciously or not, embrace environmentally friendly alternatives. This overarching premium design philosophy extends to NEXT Future Transportation, where modularity and adaptability form its bedrock. The symbiosis of these values materializes in the form of modular buses, dynamically optimizing capacity and minimizing environmental impact—a synergy of optimal function and sustainability. This synthesis continues in The Line's vision for sustainable urban living, where digitization and industrialization redefine traditional cityscapes. Here, the emphasis on renewable energy, reduced infrastructure footprint, and equal access to services for all residents signifies a holistic commitment to a harmonious future. These case studies across diverse industries showcase that design for sustainability is not just an ethical choice but a strategic one that can drive innovation, create new value and market shares, reshape consumer experiences, and redefine the post-sustainable paradigm for living. As we navigate the present challenges, integrating sustainability into the default choices of the best design holds the potential to reshape our long-term collective narrative toward a more sustainable post-transition world.

Within the framework of this paper, a blended methodology, merging literature review and case studies, has been employed. Its purpose is to elucidate the interaction of premium design across various sustainable design levels, spanning from product to service and social system spheres. The investigation delves into the potential perspectives of this approach in embedding sustainable practices within the high-end market, introducing the innovative concept of "eco-accidentalism," which promotes sustainability as the default and optimal choice for consumers. The authors aspire to provide a valuable reference for fellow researchers navigating the design strategies centered around sustainability in both ongoing and post-transition contexts. Through this contribution, we seek to stimulate further inquiry and dialogue, fostering a collective advancement towards a more conscious future.

KEYWORDS | DESIGN THINKING, ORGANISATIONAL CONDITION, EXPLOITATION AND EXPLORATION, AMBIDEXTERITY JUSTICE

ABSTRACT | This paper aims to investigate how organizations should create the conditions to facilitate Design Thinking implementation to balance their exploration and exploitation activities towards innovation. Literature has shown diverse contributions of Design Thinking to companies. However, very few have discussed one of its natures of being a mediator to nurture companies' capability to explore and exploit simultaneously and how Design Thinking implementation actions could foster this positive role. This paper has carried out a case study methodology to reflectively analyze three empirical cases in which authors have actively participated and has presented different approaches in three projects to reveal key factors that companies should take into consideration for creating the conditions for Design Thinking implementation. Implications for companies regarding the relationship with their organizational learning process have been discussed eventually. The research provides a deep understanding of how companies could facilitate Design Thinking implementation, highlighting which specific factors and conditions could enable its ambidexterity approach, especially for managers.

1. Introduction

The competitive condition of the market puts companies in the position of having to constantly find new ways and strategies to compete and succeed. According to March (1991), this condition of competitive advantage could be achieved by adopting a tradeoff between exploration and exploitation. Usually, companies are performing exploration when their activities are oriented to search, experimentation, and variation. On the other hand, companies concentrate on exploitation when there are choice, execution, and variance reduction (Lavie, Stettner & Tushman, 2010). Moreover, Levinthal and March (1993) added that the knowledge domain gives a fundamental difference between the two approaches: exploration focuses on new knowledge, while exploitation focuses on what is already known by the company. Over the years, companies often use exploitation more than exploration actions. This is because adopting exploitation brings more immediate results, and the returns of such strategies are more precise and more certain (Denrell & March 2001). However, the preference for exploitation actions alone may result in many companies needing to prepare for market changes (Fang, Lee & Schilling, 2010). In order to be truly innovative, companies need to adopt both: the real challenge is to understand how to balance the two approaches.

Balancing exploration and exploitation can be facilitated thanks to the adoption of Design Thinking (DT) inside companies. Indeed, Design Thinking has been classified as a catalyst for innovation and change by several scholars and practitioners (Brown, 2008; Forrester, 2018; Liedtka, 2015; Martin, 2009; Sheppard, Sarrazin, Kouyoumjian and Dore, 2018). Among the most established benefits are positive implications for organizational transformation and innovation (Brown, 2009), better decision-making (Liedtka, 2015), customer orientation (Kumar and Whitney, 2007) and competitive advantage (Martin, 2009). Design Thinking can act as an internal mediator giving companies the possibility to both explore and exploit (Deserti & Rizzo, 2014). The characteristic of ambidextrousness is indeed inherent to Design Thinking, given its nature of integrating deductive, inductive, and abductive thinking (Martin, 2009). This research aims to investigate how Design Thinking implementation has played a role in balancing exploitation and exploration inside companies. Moreover, it wants to underline what key factors companies need to consider creating the “conditions” to adopt and implement it effectively. The investigation is based on three empirical cases examined through three primary parameters: the design drivers, representing the strategic reasons behind the process of DT adoption, the implementation format adopted, and the organizations’ maturity in using design, looking at the grade of integration of DT. The investigation was made through participatory observation (made directly by authors) on three cases adopting DT. The authors had the opportunity to interact with the three companies for a period of 24 to 36 months.

The article is structured as follows: the subsequent section presents the adopted theoretical background, examining the evolution of exploration and exploitation processes and discussing their importance within organizations. Furthermore, Design Thinking and its importance in supporting exploration and exploitation processes are analyzed. Later, an overview of the research methodology and the adopted framework for selecting cases is presented. Then, empirical results are described and subsequently discussed, identifying five initial findings for companies when implementing DT to balance their exploration and exploitation activities. It ends with a discussion on how the proper conditions to guide companies in defining their own ways to balance exploration and exploitation activities should be set.

2. Theoretical Background

2.1 Exploration and Exploitation Towards Innovation

One of the most important objectives for companies is to sustain a competitive advantage inside their marketplace. Pavitt (2005) argued that innovation can be reached through a process of exploration and exploitation of opportunities to develop new products, processes, or services. The terms “exploration” and “exploitation” have taken on considerable centrality in organizations since their first appearance in March’s pioneering article (1991). They have become two fundamental aspects within organizational analyses of

technological innovation: organization design, organisational adaptation, organizational learning, competitive advantage and, indeed, organizational survival (Gupta, Smith & Shalley, 2006). Also, different literature started to discuss the notion of exploration-exploitation, such as organizational learning (e.g., Levinthal & March, 1993; March, 1991), organizational design (e.g. Tushman & O'Reilly, 1996), knowledge management (e.g. Brown & Duguid, 2001), adaptation (e.g. Brown & Eisenhardt, 1997), and Ambidextrous leadership (Rosing et al.,2011; Zacher & Rosing, 2015; Klonek et al., 2020). It is impossible to define a priori whether a given activity represents an opportunity for exploration or exploitation for all companies. These two concepts are often relative and have to be defined from the point of view of an individual organization. This is because specific knowledge, technology or markets may be new to one organization while already known to another.

All the literature agrees that resource-allocation constraints, organizational inertia, and desirable organizational outcomes condition the implementation of exploration and exploitation. A great debate has developed not only on the definitions of terms but also on the possibility of bringing these two processes forward in parallel within organizations. One of the main reasons for the difficulty of following them in parallel is that they require many resources. Companies don't have illimited sources, so they need to understand how they want to use them and where they need to be dedicated (Gupta, Smith & Shalley, 2006).

Anyway, since the beginning, there has been consistency in thinking that organizations need both exploitation and exploration to achieve persistent success (March 1991), so the real challenge is to understand how to balance these two processes. Some studies have suggested that "ambidexterity" (Benner & Tushman, 2003) is the answer, while others propose that "punctuated equilibrium" is the way to balance these aspects (Burgelman, 2002). Ambidexterity refers to the simultaneous pursuit of both exploration and exploitation by highly distributed and separated subunits or individuals, each of which specializes in one of these two activities. Punctuated equilibrium, on the other hand, applies to temporal rather than organizational distinction and implies that passing between cycles of exploration and exploitation is a wiser choice than pursuing both simultaneously.

2.2 Design Thinking in Organizations for Balancing Exploration and Exploitation

Design Thinking, as an innovation approach, is implemented to propose valuable ways to capitalize on organizations essential resources and generate experimentally cutting-edge solutions and changes. Design Thinking (DT) was born to codify how designers see and think (Liu, 1996). Nowadays, among the different sources, there is not a specific and precise way to define it, and its concept is broad (Cooper, Junginger & Lockwood, 2009). Many different debates take place around DT, about what exactly it means and what the differences are from other methods and processes such as creativity, innovation or systems thinking (Kimbell, 2009). The literature agrees it is an iterative and exploratory process (Braha and Reich, 2003) used to solve problems, guided by human-centeredness (Junginger, 2009; Liedtka, 2015; Dunne, 2018).

During the last two decades, DT has been critically analysed by scholars from design, business, and innovation management disciplines. It has been identified as a "powerful, effective, and broadly accessible" approach to innovation that can be integrated into all aspects of business and society" serving the purpose of "generating breakthrough ideas" (Brown, 2009). Recent literature, both from Design and Management scholars, consolidates how DT adoption brings positive implications for organizational transformation and innovation (Brown, 2009), better decision-making (Liedtka, 2015), customer orientation (Kumar and Whitney, 2007) and competitive advantage (Martin, 2009). An increasing number of organizations are aware of the potential to integrate and appropriate DT internally; contaminating the corporate culture with new practices can support how business approaches changes and innovation processes, such as balancing exploitation and exploration. The dual nature of the DT approach is strongly linked with the concepts of ambidexterity within businesses; DT adoption can play the role of the internal mediator, generating a fertile ground for companies to simultaneously explore - dealing with the uncertainty of the front-end innovation - but also exploit - dealing with the development of product and or services (Deserti & Rizzo, 2014). The ambidexterity in DT derives from the different thinking models that it embraces: one of the crucial characteristics of DT consists of combining deductive, inductive and abductive

reasoning (Martin, 2009); this is not only a pivotal aspect to bringing Design Attitude within organizations (Michlewski, 2015) but also a way to balance exploration and exploitation helping the established organization to reduce the typical “bias toward reliability” (Martin, 2009; Sutton, 2001). Ambidexterity may be created by dedicating a portion of the enterprise to DT. At the same time, the rest is based on exploitation or instilling a widespread mindset of DT that includes all of the company's components in the exploration activities. More specifically, it is worth illustrating the different aspects to consider when defining the various cases of DT adoption in organizations.

Most of the adoption cases of DT are recognized under the label of innovation activities or labs; however, the strategic reasons - the design drivers - behind the process of adoption are multiple, as effectively summarized by David Dunne in his last book “Design Thinking at Work: How Innovative Organizations are Embracing Design” (Dunne, 2018). For most, it is about facilitating a disruptive innovation path or improving better experiences for customers; an increasing number of other goals more oriented to internal cultural development for changing internal mindset or feeding internal teamwork across the organization silos, or also to retain and attract talent and valuable people; at last for some, adopting DT has the aim of activating a system change organizational and social (fundamental changes). Businesses might combine different reasons to implement DT, usually following a gradual process of integration of design into organizational life (Buchanan, 2015), starting from tactical issues arriving to vision and strategy passing by organizational problems of operation.

The other crucial factor to consider is the placement of the Design Thinking provider, internal or external (e.g., design consultancies). Different “placements” correspond to a variety of forms through which organizations adopt DT. The internal DT adoption forms vary from established innovation labs with designers - design units - recruiting designers in strategic positions or building the DT competence of existing employees through dedicated educational programs. The pure external DT adoption models include all the typical forms of design consultancy activities to support the adoption of DT in the organization: design sprint sessions, long-term projects, training programs, or other forms of design consultancy activities. The organizations choose the adoption model depending on their goals, culture, innovation strategies and sizes.

3. Methodology

DT adoption can guide companies in dealing with uncertainty in innovation - exploration and fostering the development of products and services - exploitation (Deserti & Rizzo, 2014). Therefore, this paper aims to understand how DT implementation has played this role and what key factors companies need to consider creating the “condition” to adopt and implement effectively. The case study method (Yin, 2009) has guided the research to analyze three cases in which authors have carried out DT implementation. In each case, the data has been collected through participant observation (Gatt and Ingold, 2013; Gunn et al., 2008) by the authors’ empirical research actions. The authors refer to this as not a detached form of observation but a close look at the engagement understood and responded to by the people involved in the research.

3.1 Case Selection

Three projects have been selected for empirical research actions, and authors have applied the following criteria of selection:

- Authors have participated directly in all three projects as an external expert team, who brought design thinking from outside and implemented it inside the companies;
- The methodological approach and methodology used in the projects is the same in all three cases;
- Organizations in all three projects are big companies which have a large internal structure and huge numbers of employees;

- In all three cases, design thinking activities have been conducted with the involvement of actors at the companies' strategic level;
- All three projects have been for a long period, between 24 - 36 months.

3.2 Framework for Case Analysis

The main indicators extracted from the literature that have guided the inquiry in the three cases are design drivers, the format or means of DT implementation, and the organization's maturity level of understanding and using Design.

Table 1. Case study framework (elaborated by authors).

Indicators	Contents
Design Drivers (why)	improving better experiences for customers or internal actors retain and attract talent and valuable people facilitating disruptive innovation path changing internal mindset (design culture) activating a system change
Format/Means (how & what)	design sprint training - dedicated educational programs create internal design unit/lab/hub recruiting designers in strategic positions long-term project collaboration
Design Maturity	design or design thinking is not considered an essential skill for companies' development design is used as aesthetic and functional skills for tangible outputs design thinking is acknowledged as strategic advantages

3.3 Innovation Stories in Three Cases

The design thinking activities conducted in each of the three cases will be presented and analyzed using the conceptual framework presented above. The following table has summarized the initial design drivers, the primary format of DT implementation actions, and the design maturity of each case to show the differences and similarities.

Table 2. Elements in the framework presented in each case (elaborated by authors).

	Initial design drive	Main formats	Design Maturity
Case One	Facilitating disruptive innovation path	a. Explorative projects b. Training activities	Design was used as aesthetic and functional skills for tangible outputs
Case Two	Changing internal mindset (design culture)	a. Explorative projects b. Training activities	Design thinking was acknowledged as strategic advantages, and operationally involved at the strategic level
Case Three	Improving better experiences for internal actors; Retain and attract talent	a. Practical projects b. Training activities	Design thinking was acknowledged as strategic advantages, but not yet involved at the strategic level

Case one: Implementing design thinking in a traditional Chinese furniture company.

The first project is an ongoing project between the authors and a Chinese furniture company that has been running its business for over 20 years. The initial collaboration aim was to find a new approach to facilitate innovation inside the company, not only at the product development level but the companies' strategic level. Thus, the drivers at the basis of this activity are facilitating a disruptive innovation path but also kicking off a process of internal cultural development.

The collaboration started with introducing an external Design Thinking team, composed mainly of authors, the company's CEO and managers of R&D to the whole company. The initial activities were explorative research projects and training courses for the company's managers and designers. The research projects in the first year were aimed mainly at collecting up-to-date resources and information on furniture and related sectors internationally and transforming them into thematic topics and directions for the company's internal R&D team (design teams included). On the other hand, the training course has been carried out twice. The first time, selected design managers and designers came to participate in training activities in the authors' institute (physically outside the company and their daily working routine and environment); the second time, the authors dedicated five days to the company and organized intensive training workshops with selected managers and designers (physically inside the company). All the activities have been strongly supported by top-down policy and guaranteed commitment from participants.

The second year's collaboration has been planned based on the first-year experience and has retained the two approaches: project-based and capability-building through training. Authors have worked on moving towards understanding the company's structure and logic, as well as exploring potential opportunities of intervention. The main collaborative actions were mixing and integrating two types of DT activities in order to have a coherent and effective result. The design methods and tools produced in the collaboration projects have also been taught to participants (employees) in the training so that they can apply them to practical challenges and problems. The main outputs of the second year's collaboration are strategic design guidelines for new product development, design research guides, and the launch of the joint design centre with the authors' institute inside the company. The idea of the third year's collaboration will then focus on supporting the building of a research centre abroad, which will strategically position as a bridge to link European resources and DT experts with the headquarters, as well as the recruitment of talents from abroad.

Case two: Design thinking training activities for a Japanese company in the telecommunication sector.

The second project was an activity implemented for four years between the authors and a Japanese company leader in the telecommunication sector. The initial collaboration was aimed to identify possible ways in which design can act as a boost for the implementation of innovation strategies across different levels of the company. The drivers at the basis of this activity are facilitating a process of internal cultural development but also retaining and attracting valuable people.

Firstly, during the first year, the authors were engaged to do explorative actions, supporting some level of the company in finding new possibilities for their company. New thematic topics and directions for the company's internal R&D team (design teams included) were identified. Then, during the other three years of collaboration, a series of training courses for the company's managers and designers were provided. All three years of courses were attended by design managers and designers selected by the Japanese company. For the second and the third year of the collaboration, attendants come to Italy, inside the authors' institute, to participate in training activities. The training activities were held for three weeks, each week, with five days of training per week. During the fourth year of collaboration, the training was held inside the headquarters of the Japanese companies, where the authors were invited to provide the training in-house. Here, the authors have provided training in five days using the format of workshops where selected managers and designers were also invited. All the activities have been strongly supported by top-down policy and guaranteed commitment from participants.

As mentioned above, the first year of activity, through research activities, was dedicated to mixing and integrating two types of DT activities. In particular, the focus was on both elaborating strategic design guidelines and creating design research guides. The objective of this first year of collaboration was to

understand how design can support different levels in finding new areas of development. During the other three years of collaborations, working through training formats, the activities focused on various aspects. One of the objectives was the training of international employees coming from different centres of the company operating in different parts of the world. Another objective was the development of a design culture through a general understanding of what design is and its evolution. Moreover, the training aimed to integrate design thinking methodologies and contents, developing first attempts through training workshops. Finally, the last objective concerned the development of a new process to use inside the company, integrating DT and scenario-building techniques. All training aimed to bring a design thinking approach into the company through training of essential stakeholders, experimenting with it since the courses where practical proposals were developed.

Case three: Design thinking implementation in a Corporate and Investment division of an Italian bank

The third case consists of a long-term design-based research project in collaboration with the Human Resources unit within a leading Italian bank. The trigger of this collaboration is to explore how DT adoption can improve the quality of the working life of employees. Thus, the drivers at the basis of this activity are: improving better experiences for internal actors, the need to retain and attract talented people, and also to kick off a process of internal cultural development. Thus, the HR management team invested in setting up a completely new operative team called People Experience, which literally has to design the "employees journeys". People Experience aims to design micro-experience that can reflect on macro-experience in order to promote organizational culture and make tangible the value offered by HR to the whole division. The strong commitment of HR and its awareness of the value of adopting DT facilitate the research collaboration. The authors perform an active role in all the different iterative steps of the project.

At first, the project focuses on understanding how to intervene through designing the employee experiences: mapping the state of the art of the employee lifecycle in this bank, understanding the context in which the DT project should land, and moreover, understanding the role of the DT implementation. This phase of the activities is named Scoping and permits the authors to redefine the shared direction of the project collaboratively with the company. Indeed, there a need to produce a permanent and long-lasting impact within the organization's routines; thus, the redefined focus consists of gradually fostering proactivity and an employee-focused vision (human centricity) within the HR unit first to finally promote and make the organizational culture tangible to the whole company. This passes by working on creative confidence (Kelly & Kelly, 2013) of employees, starting from enabling the People Experience team to develop qualitative human experience.

The means to initially address this challenge is a process of applied training dedicated to HR members of the company to feed the internal design culture through specific DT training activities. This phase of activities is called training and is divided into different phases, which gradually involve various actors in collaborative activities. Indeed, the ecosystem of actors involved is articulated in progressively bigger circles: the plan is structured in this way, aiming to effectively integrate the DT into the routines of the division, thus gradually impacting the internal client experience and the whole organizational culture. The approach that stands as a theoretical reference is to set up a process that activates a progress loop (Amabile & Kramer, 2011): make the employee touch the meaningful progress of each small step iteratively. This set of training activities takes place in multiple "Experience Design Lab" dedicated virtual places developed as a learning area for the employees involved in each step. After the first year of activities, mostly devoted to training, the project moves to a phase called Implementing. During this third cycle of activities, the DT implementation enlarges its scope to a wider audience. Indeed, the project finally arrived to propose exploratory solutions to define a new way of working life experiences after the COVID-19 pandemic.

4. Research Findings

The authors have reported on three projects to present how DT implementation has contributed to guiding companies in balancing exploitation and exploration. They have followed three different innovation paths and strategies; however, some common findings have been observed.

4.1 A "Reframed Brief" is Necessary to Guide DT Implementation Effectively

All three projects have started with requests from big companies to bring DT inside towards fostering innovation. All three companies have acknowledged the contributions and importance of DT, and all of them have considered DT to fit their development needs and desires they had in mind. However, none of them had a clear idea of the "proper ground" that DT could initially land inside the company as a "newcomer". The question is what DT could or should intervene and how DT could fit and effectively support the company's vision in the long term. In all three projects, the authors have spent a certain amount of time understanding who the companies are, their strengths and weaknesses, and their real challenges and problems.

In case one, after the initial collaboration request arrived, the authors physically conducted a visit and field trip to the company, which helped them gain a precious first-hand understanding of the company. This activity has modified and reset some parts of the collaboration plan (e.g., project topics) and expected results. In the second case, one part of the first-year collaboration was understanding how DT could intervene at different company levels to define new business opportunities. In the last case, the first phase was dedicated to defining the collaboration scope (e.g., project typology and potential areas) and checking the coherence between DT intervention and the company's needs. "Reframing" (Dorst, 2011; Cross, 2006; Kolko, 2010) has often been considered one of the main characteristics of Design Thinking. When conducting DT implementation, the reframing action not only plays a role in defining opportunities and solutions but, more importantly, enables the identification of real problems or challenges and sets the "proper" brief. Authors' practical experiences could tell that it is essential for companies who have an interest in implementing DT and external DT teams to take time to know each other, to share visions and opinions on approach and expectations, and to create a "situated" path for companies to benefit from DT before conducting concrete DT activities. This guarantees effective adoption of DT with a long-term vision and profound impact.

4.2 Design Training is an Effective Way to Implement DT, Contributing to Building Individual Capability Related to Exploitation and Exploration

Training activities have been carried out in different forms in the three projects, and it has been observed that big companies are willing to invest in talent capability building, especially the soft skills related to DT. The frequency should be well-planned. Stimulating internal culture development through DT training is a way to foster the condition to make DT approach adhere to the organizational context, as well as to align employees with this new approach from the mindset to operations. Furthermore, due to its feature and applications model, DT capability is only possible to learn and obtain with practical experience. Therefore, training activities provide a "ground" to try, do and learn. One difficulty or potential risk is that sometimes companies can struggle not clearly seeing the link between training outcomes and improvement on traditional/core business, especially when many of them started with an objective more related to exploration. Authors have dealt with this issue in all three cases through active communication among different actors at different levels, setting different parameters to evaluate the results and visualizing progress.

In the first project, training was a part of the initial collaboration ideas for organisations to gain DT skills, methods and tools. The training actions aimed to broaden employees' innovation views and equip them with a systemic approach. The training topics are highly related to the companies' core business and sector. Training activities are a significant part of DT implementation in the second case. The company has

chosen a new topic to work on, but the focus was on transferring the DT mindset, methods, and process to the participants. In the last case, training activities entered into play at the second phase and were oriented by project development needs thanks to the reframed brief. It has guided the company to link its initial exploration objective of implementing DT to generating results that could impact its core business.

4.3 Actors' Engagement at Different Levels and Positions Facilitates DT Implementation

It is important to engage stakeholders, from managers at the high level and at essential decision-making positions to individual employees at the basic operative level, in the DT implementation process towards transferring design intervention to design integration within the organization (Wrigley, Nusem & Straker, 2020). Rauth, Carlgren and Elmquist (2014 b) have stated the necessity of establishment legitimacy for gaining acceptance and support for DT implementation in organizations. Therefore, the engagement of

very top-level decision-makers, e.g., CEOs and directors of essential departments, could play as the endorsement to "welcome" DT. However, that is far more than enough. From project experiences, authors have understood that the challenge of effective implementation of DT is also about how employees perceive and practically benefit from it. Engaging them in real experience is necessary to make sense of why this approach and method will be helpful and should be integrated into their daily working activities.

In the first case, DT implementation has involved product designers, marketing researchers, design managers, the director of the R&D department, the marketing and communication department and companies CEO in different phases during the process. The engagement also enables these actors to understand among themselves: their different roles and perspectives towards a shared objective, as well as how the DT approach could support their work and tasks. In the second case, the design director, who acted as ambassador to introduce an external DT team (mainly composed of authors) within the company, selected employees with very diverse backgrounds (both cultural and professional) to participate in the DT training. In DT implementation activities, they shared perspectives and knowledge through collaborative learning. In the third case, DT is also welcomed from a top-down approach, guaranteed by the top managers. Nevertheless, the practices have enlarged from small groups to various departments and positions, which allowed diverse employees to take part in experimenting and interacting with situated DT methods and tools and providing their personal feedback as well as obtaining their personal learning results.

Therefore, involving actors and stakeholders of the company enables DT implementation to facilitate systemic change within organisations, both vertically and horizontally. These interventions are seeds for gradually cultivating a design culture inside in the near future.

4.4 Dedicated Physical and Digital Spaces for Practising DT

The notion of having physical spaces as an element for supporting the success of DT integration is documented in the literature (Leifer &Steinert, 2011; Dunne, 2018; Wrigley, Nusem & Straker, 2020). The dedicated spaces could isolate employees participating in DT activities from their daily working routine and tasks to feel safe to try, experiment and make mistakes, which are necessary to obtain the DT mindset and approach. These spaces also act as playgrounds or gyms for DT learners to do exercises and practices to train their DT minds and actions gradually. It is essential to specify that the dedicated spaces don't refer to the fixed physical ones. They correspond to the different DT implementation activities and formats. Due to COVID-19, many digital versions of dedicated spaces have acted actively in providing virtual spaces to substitute for conventional spaces.

In case one, in the beginning, DT actions have taken place outside the company, or the company has created specific rooms dedicated to particular DT activities. From the second year, a joint design center has been created to build an internal ground for cultivating DT initiatives, continuous DT practices, and a design culture. In the second case, most of the DT implementation actions in the second and third year have been conducted in a learning space inside educational institutes, where DT experts and all

participants (employees) frequently interacted and worked together for a certain period (around four weeks). In the third case, the “Experience Design Lab” - a temporary “digital” design lab with fixed scheduling- was created inside the company as a virtual learning area for involving employees in each step of the DT activities. However, the critical challenge is linking what is experienced in the “dedicated space” to a broader range of the organisation's audiences, actors, and stakeholders. This space should also deal with the request of being “open” and “connected” to other parts of the organizations. Companies should make use of the produced outputs, generated atmosphere, and reflections and effectively connect them to face other organisational challenges.

5. Discussion and Conclusions

The paper identifies a set of empirical directions to consider in setting the proper conditions to guide companies in defining their ways to balance exploration and exploitation activities through the support of DT adoption. These directions emerge from the analysis of the findings and their discussion in relationship with the extant literature and practitioners’ contributions.

As confirmed in the literature, DT adoption plays a mediating role between exploration and exploitation. DT is an “ambidextrous” approach by nature, generating a fertile ground for fostering companies’ ambidexterity. The empirical results obtained during the research projects present how the DT implementation can combine both “ambidexterity” with a “punctuated equilibrium” in an organization. Indeed, in various cases, DT's implementation makes the organization simultaneously deal with novel challenges by exploiting internal routines and resources. This happens, including multiple organization's units and individuals in the various moments of the exploration activities; the critical aspect involves various actors but in different and alternated experimental cycles of activities. This can be defined as an evolving path to gradual ambidexterity: business can be guided in gradually being ambidextrous thanks to DT's support that nurtures a specific type of (design) culture within the organization. As it happens in the process of DT adoption in organizations, a gradual integration process (Buchanan, 2015) can be the solution to permeate the organizational life effectively.

To make this process effective, it is fundamental to support the organization in being open and prepared to welcome changes to nurture resilience (Hamel & Välikangas, 2003) in the organization, thus proactively adjusting in front of an uncertain future. Indeed, DT implementation should start with a set of activities dedicated to facilitating a mutual understanding between the DT provider and the organization in question; as presented in the findings part, before conducting any activities, it is critical to comprehend the organizational context and cultural aspects deeply. This is why the first cycle of exploratory activity can often start in a dedicated space among the company components; this safe zone to experiment gradually can stimulate a more expansive area, merging its results with the more operative and routinary activities within corporations.

From a sustainable point of view, to balance innovation activities on exploitation and exploration, organizations should not only rely on external resources and support; it is crucial for them to gain the capability and gradually deal with it by themselves. By nurturing internal culture development, organizations acquire and internalize new knowledge that will make them more capable of autonomously facing changes. Even in this sense, DT implementation acts as a means to activate a matching process between exploration and exploitation.

Therefore, all the different DT activities inside organizations aim to nurture a knowledge transfer from external DT providers to internal receivers through capability building. In organizations where DT's values have not been well recognized and acknowledged, the knowledge transfer process should start with an introductory phase to relate DT to the pre-existent one in organizations (Aklin,2011; 2013) and to articulate the objectives, typology of actions and detailed plans. Actors (companies' employees) at different levels and positions should all be related or involved in the transfer process to be aligned.

The adoption of DT must be considered in a specific and situated context: it cannot be considered a model for organizational change that can be applied indifferently in any context or situation (Gero, 1998). Therefore, a critical reflection must be made on the conditions that characterize the context of the implementation of this kind of approach to innovation. Company factors such as the significant dimension, the vital need and tension of change, and the presence of knowledgeable top management ease and accelerate the contamination process with DT in the corporate context. DT must not be intended as the purpose of the innovation but instead, as a means through which innovative purposes are achieved. DT can act as an engine of change; DT adoption may play a critical role in activating static organization processes to exploit internal resources and actively explore uncertain paths.

About the Authors:

Xue Pei is a researcher (Assistant Professor), Department of Design (POLIMI). Her research focuses on applying design (thinking) approaches and methods as a strategic catalyst to fostering innovation. Currently, her work addresses developing design-driven strategies towards sustainability in the furniture sector.

Gianluca Carella has a Ph.D. in Design, his research focuses on how to use design inside organizations to create innovation. Also, he is working on projects that deal with design-driven entrepreneurship. His main streams of research are on Strategic Design and Design Management.

Michele Melazzini is a researcher (Assistant Professor), Department of Design (POLIMI). His research topics include strategic design and design management. Research activity focuses on the role of design in organizations: the design interventions affecting organizational transformation.

Acknowledgements: We would like to thank Prof. Francesco Zurlo for his support as the scientific coordinator in all three research projects and all the people who have participated in the research projects.

KEYWORDS | INNOVATION LABS, DESIGN RESEARCH LABS, PUBLIC INNOVATION LABS, DESIGN FOR PUBLIC INNOVATION

ABSTRACT | The digital transformation of the public sector promotes collaboration and experimentation. Furthermore, it paves the way for design practices to enter new realms. Creative approaches, such as design thinking, service design, and system design, have surfaced, particularly within innovation laboratories. However, these organizational structures often face challenges related to achieving and executing changes, transferring knowledge, and gaining cultural acceptance. The structure of public sector innovation laboratories aligns with that of the private sector, where the phenomenon originated. Nevertheless, their primary missions differ: one focuses primarily on the common good, while the other prioritizes commercial interests. In contrast, the concept of Design Research Labs (DRL), rooted in the arts, shares a mission to serve the public interest, offering a different perspective on labs in the public sector. As authors, we explore what a DRL framework might offer to support public sector innovation labs. The paper serves a dual purpose: first, to develop a systematic understanding of the criteria for DRLs; second, to propose areas of tension and fields of action for what public innovation laboratories can learn from DRLs as a framework. By offering this new perspective, the article contributes to a better understanding of the characteristics of public labs, facilitating positive change.

1. The Rise of Public Innovation Laboratories

In the past decade, the landscape of innovation laboratories has flourished in various forms across different sectors (Bason, 2014; Mulgan, 2007). The rapid expansion in the public sector can be justified by the realization that traditional structures, practices, and approaches in politics and public administration may not adequately address contemporary challenges, including climate change, social justice, and shifting demographics (Ottenbacher & Dubé, 2018). This growth has also sparked a shift in the approach to strategy and implementation as well as an increased demand for cultivating creativity, collaboration, and prototyping (Graham & Milligan, 2019; Werneck et al., 2020; Wellstead et al., 2021; Pinder et al., 2017; Komatsu et al., 2021). Simultaneously, the term labification, as coined by Williamson (2015), underscores the temporary nature and the associated sense of a trend that brings high expectations and an element of the unknown.

This begs the question: do innovation labs hold more significance than merely being a passing trend?

1.1 Scattered Landscape of Forms, Missions, and Impact

The landscape above includes various forms named differently from policy labs, city labs, gov labs to social labs (Whicher 2021; Hinrichs-Krapels et al. 2020). Blazing an early trail was Denmark's MindLab, a cross-governmental innovation unit that involves both citizens and businesses, founded in 2002. It heralded a culture change in the Danish government, which labs around the world have attempted to replicate, but it was closed in 2018. While MindLab still serves as a great example, the BMZ digilab hardly operated for two years before the physical workspace space was converted into a modern meeting room. Reasons have been multiple, among them: first, a changing political party leading the ministry with different priorities. Second, the mission of the lab, to scale digital innovation, has not been easy to grasp for employees who were mostly new to digital transformation, and third, the team was built out of four institutions not equal in terms of resources, power structures, and mutual dependencies. These circumstances offer possible insights into success factors for public innovation labs. Another example is the Denkfabrik, an innovation laboratory founded in 2018 within a federal ministry in Germany, that transitioned to a department within the ministry in 2022. In addition, the CityLab is funded by the Berlin Senate Chancellery. It is designed as an open space and a point of contact for citizens and administrative employees interested in digitalization and combines elements of a digital workshop, coworking, exhibition, and event space to create a place where participation and innovation are conceptually combined. From a design perspective, the CityLab is clearly focusing on the first phase of ideation and prototyping; afterward, the city of Berlin should take over.

At first glance, those examples suggest the impression that setting up new organizational forms such as innovation labs is already perceived as a widely spread, and approved strategy to enhance change in the public sector. Nevertheless, forms, structures, missions, and expectations towards innovation labs are different and partly conflicting.

Most initiatives so far prioritize aspects such as new work methods, process design, digital tools, and workspaces, while elements like outcomes, key performance indicators, iterations, connections to innovation ecosystems, and competence models receive less attention. However, even though the number of innovation labs is increasing, a comprehensive theoretical foundation is still lacking. This scattered map might indicate the unknowns and one reason why labs often struggle to become a sustainable approach to contributing to changes.

1.2 Emerging Design Practices

The intersectoral expansion of design practices since the rise of design thinking has led to new roles for design as a discipline and new contexts for professional designers, particularly in the public sector and policy design (Villa Alvarez, 2022a & 2022b). Advancements in practical implementation suggest that the introduction and application of design practices often hinge on the expectations a methodological manual

provides to non-designers. Practical observations also reveal that its foundational principles, including problem orientation, user questioning or observation, and a prototyping approach (learning through trial and error), are novel for many workers in administration and often contrast with established performance characteristics such as predictability, the insistence on correctness, risk aversion, and the need to substantiate claims. Furthermore, the prescription of design (thinking) as a method comes along light-footed without emphasizing a systemic, holistic problem-solving approach. However, for newcomers, the toolboxes and method cards published during the emergence of design practices can create the impression that they can be applied without prior knowledge or adaptation to the specific context (Augsten, 2022).

Some design researchers proclaim that the application of design thinking as a method has split the role of professional designers from design practices and made it applicable to everyone through training. The final aspect has naturally faced criticism from professional designers who are concerned about its relevance and its place within the design community. Without ignoring these ongoing discourses about the transdisciplinary role of design (Hepburn, 2022; Peukert, 2021 & 2022), we as authors represent the position that the expansion and adoption of design thinking have been promoted by the toolisation approach of Stanford's design thinking version but have positively positioned design practices and professional designers in the context of innovation and facilitation (Augsten & Gekeler, 2017) as a predecessor for today's appearance in the public sector (see Schaminée, 2018).

1.3 The concept of labs in the design discipline

Scientific institutions, such as universities focused on art and design, often establish labs with names like Design Labs, or Design Research Labs (DLR). These labs have been recognized as agents of change and serve as spaces for experimentation and exploration in the context of organizational transformation. They attract individuals with foundational skills and experience in design practices and principles. Importantly, these labs existed long before the term labs gained popularity.

While these labs are hardly mentioned in design research discourses, they might offer new possibilities for the concept of public innovation labs. For instance, DRL holds promise in providing interdisciplinary knowledge transfer that supports impact-driven research, making it relevant for practitioners and multiple stakeholders. However, there is still a notable gap in design research when it comes to systematic investigations into the potential and criteria of DRLs.

In this paper, as authors, we aim to shed light on two key aspects. First, we seek to gain a better understanding of what a DRL entails, the role that design plays within these labs, and how it functions. Second, we aim to explore what lessons can be derived from DRLs for public innovation labs.

2. The Undefined Landscape of Design Research Labs

The number and significance of these labs have been on the rise, yet they have remained a relatively unexplored area in design research. The term and concept of DLRs first emerged in the UK during the 1960s, following the Design Method Movement (Alexander, 1977; Schön 1969; Jones 1970). However, it is in the early 2000s, particularly in the European context, especially in the Netherlands and Scandinavian countries, that DRLs have continued to evolve and gain prominence. The Helsinki Design Lab, closed in 2013, needs to be mentioned as a pioneer and still leading example. It accelerates the integration of design and government by establishing strategic design as a core discipline in supporting governmental decision-making and service delivery.

A current trend is the growing number of DRLs in German-speaking regions, with examples like Burg Labs at Burg Giebichenstein University of Art and Design Halle, Kind-Lab at the University of Applied Sciences Trier (among others), Hybrid Things Lab at the University of Applied Arts Augsburg, the Design Lab for Applied Research at Technical University Dresden (in collaboration with Fraunhofer-Institute). This growth is also mirrored on an international scale, with DRLs such as the DESIS Lab at the Parsons School of Design, MIT Media Lab at Massachusetts Institute of Technology in Cambridge, USA, Design Labs at Harvard University

Graduate School of Design, Diseno@QUT Design Lab at Queensland University of Technology in Brisbane, Australia in collaboration with universities from South America, or the Social Design Lab at Victoria University, School of Design Innovation in Wellington, NZ. The rise of labs can also be recognized in the global south. As one example among many, the Design Lab in Kigali, Rwanda, established in 2020 as CcHUB's Research and Development Unit, aims to bring design into the way public agencies and large corporations think about the implementation and use of technology to solve significant problems in society.

These labs share a focus on radical innovations to tackle complex social, political, ecological, and technological issues. They aim to generate new ideas that benefit the public, like DLRs and public sector innovation labs. With the growing urgency and complexity of these challenges, more DLRs in design schools and interdisciplinary settings, especially in the public sector, are likely to emerge in the future.

2.1 Theoretical Understanding and Characteristics

This evolution has been relatively unexamined in theoretical design discourse. While the potential and the role of design in interdisciplinary lab structures are increasingly recognized, there has been a lack of systematic research.

The first theoretical discussions can be traced back to Binder and Brandt (2008), who introduced the term in the context of design education. Their paper explores the concept of a design lab as a platform for conducting participatory design research, emphasizing the collaborative and interdisciplinary nature of design activities

within such a setting. It discusses the benefits of this approach for fostering creativity, innovation, and engagement among various stakeholders in design processes.

Since Binders' research in 2008, no further analysis, classification, or mapping of design labs has been published. Therefore, the purpose of this paper is to inquire about the role of design and design research labs, with the aim of developing a new perspective. This serves a dual purpose: it provides a framework for DLR to support the future impact of public innovation laboratories and sheds light on aspects overlooked in the field of design. Despite its potential to offer valuable insights not only for the public sector but also for design research itself, there is still a lack of updated and systematic investigation in this area. In the following paragraphs, we will propose four principles of the DLR framework before applying them to the public sector.

3. The DLR Framework for Public Innovation Laboratories

3.1 Theoretical Foundations of the Framework

The underlying definition of DLR in this paper is based on various sources: Binder and Brandt (2008), Binder (2007), Reynolds-Cuéllar (2020) or Boyer (2020). Binder and Brandt derived characteristics from a traditional lab as a metaphor, based on the practical example of the Malmö Design:Lab, defined in the paper as follows: "The Design:Lab is neither a particular set of methods and techniques nor a particular place or event; it is a platform for a collaborative inquiry that is based on design experiments" (2008, p. 121). We, as authors, use the term DRL in this paper as a comprehensive umbrella term that combines three fundamental characteristics: A DLR …

- is primarily affiliated with design schools and departments;
- explicitly applies design practices as a tool and method for inquiry; and
- is addressing emerging societal, technological, and ecological challenges.

3.2 Methodological Approach and Practical Use Cases

This definition laid the foundation for an investigation into existing DRLs associated with design schools. Our methodology involved a qualitative pattern analysis of four distinct design labs from various global

locations. This analysis was conducted by gathering information available online and visually mapping the data, which was a collaborative effort between both authors.

In the initial step of our methodology, we delved into the self-descriptions and profiles of the selected design labs to uncover shared traits and unique characteristics that define these entities. This allowed us to identify commonalities and distinctions among them.

Subsequently, the mapping process was enhanced through the utilization of guiding questions. They served as a framework for our analysis, enabling us to delve deeper into the structural aspects, functions, and purposes of each DRL. This comprehensive approach provided us with a holistic understanding of the design lab landscape, which we will further elucidate in the subsequent sections of this study:

Table 1. Guiding questions for mapping process.

What does the DRL?	Describing the aims, goals, and fields of actions of the DRL.	e.g.: aligning design practice with societal issues
Who is part of the DRL?	Describing the stakeholders involved directly and indirectly in the DRL.	e.g.: research partners, collaborators, and affected groups
Why is the DRL operating?	Describing the missions of the DRL.	e.g.: specific societal issues, and design research questions
How does the DRL operate?	Describing the structures, processes, and operating principles.	e.g.: theme-based organisational structure, research portfolio
Where does it operate?	Describing where the DRL is operating.	e.g.: local or international level, facilities of the lab

Through rigorous discussion and an iterative open coding process, we derived four fundamental principles from the dataset, which subsequently formed the basis of the framework (see figure 1). This framework represents a significant outcome of our research, serving as a conceptual structure for understanding and analysing DRLs and their impact.

It is important to note that this framework is not static; rather, it serves as a prototype that will be subjected to empirical testing and refinement, aligning with the dynamic and evolving nature of DRLs and design research.

Furthermore, to illustrate the practical utility of the framework, we present four case studies of DRLs that exemplify its application in real-world contexts. These case studies showcase how the framework can be employed to gain insights into the functioning and significance of DRLs, demonstrating its potential as a valuable tool for both researchers and practitioners in the field of design and innovation.

The Design Research Lab, affiliated with the Berlin University of the Arts (UdK) since 2010, is a collaborative network involving UdK, the Einstein Center Digital Future, the German Research Center for Artificial Intelligence, and the Weizenbaum Institute. This network defines itself as “a network of individuals, organizations, and non-human entities engaged at the intersection of technologies, materials, and social practices” (Design Research Lab, 2023). Their objective is to create socially and ecologically sustainable tools, spaces, and knowledge that promote people's participation in a digital society, with a foundation in inclusiveness and respect for the environment. Their mission is to democratize technology development by fostering collaboration across academia, industry, politics, art, design, activism, and the public, making “technology development a participatory social practice” (ibid.). They are structured around four theme-

based working groups (material interaction, smart textiles, social design, and digital sovereignty). Their interdisciplinary approach incorporates “critical human-centered design, technology hacks, prototyping, public interventions, and strategies for inclusive discourse” (ibid.) and aims to introduce innovative forms of transdisciplinary research.

The Parsons Design for Social Innovation and Sustainability Lab (DESIS Lab) was founded in 2009 at The New School in New York City and is part of the DESIS Network, a global group with around 50 design labs. It describes itself as an “action research laboratory” that “works at the intersection of design and social theory, applying interdisciplinary expertise to sustainable practices and social innovation” (The New School, 2023). The vision and mission of the lab revolve around the advancement of design-led social innovation, with the aim of creating more equitable and sustainable cities and practices. In response to the intricate and interrelated global challenges, the DESIS Lab concentrates on issues like indigenous sovereignty, planetary interdependence, diversity, natural systems, societal inequities, and the commons. To achieve these goals, the lab employs “integrated design practices,” placing a strong emphasis on “service design as a practice based on social justice principles” (ibid.). The lab actively seeks interdisciplinary collaborations, both with local partners in New York City and global partners within the global DESIS Network.

The Delft Design Labs (DDLs) were created in 2017 at the Faculty of Industrial Design Engineering (IDE) of TU Delft. They describe themselves as “platforms for design innovation and knowledge development in which staff members of IDE, students of TU Delft, and external partners work together” (TU Delft, 2023). Their main aim is to involve IDE students in research to contribute to design research while addressing a broad range of societal challenges.

These DDLs are organized in a flexible, open setting framed by four main themes: sustainability, health and well-being, mobility and urban living, and artificial intelligence, which form the basis of a total of 17 theme-

based labs. These labs “are driven by the passion of individual educators and researchers” and follow a practice-based understanding that “shows concrete examples of how issues are studied, insights are gathered, and challenges are addressed through design interventions” (ibid.). The open structure of the DDLs encourages collaboration across disciplines and allows adaptation to changing societal needs.

The Social Design Lab (SDL) was established at the School of Design Innovation Department at Victoria University of Wellington, NZ. The SDL is driven by the acknowledgment that “over the past decade, the role of design and designers has undergone a major shift as the discipline re-evaluates its contribution to society and the environment” (Victoria University of Wellington, 2023). SDL aims to promote the evolving role of design in contributing to more positive, equitable, and sustainable outcomes for society and the environment. Against this background, SDL focuses on enhancing students' critical and creative thinking, communication skills, and cross-disciplinary collaboration to prepare them as socially responsible designers and leaders. As a key characteristic, SDL integrates local and indigenous knowledge into its research and employs ethnographic and participatory approaches to develop design solutions for pressing social and cultural challenges. The SDL is organized around three “research pods”, defined as social design, social impact, and social innovation and form the basis of three different research projects.

Even though these four examples exemplify different approaches and thematic focuses of DRLs, they also serve as compelling illustrations of the fundamental commonalities that underpin the diverse landscape. In the ever-evolving field of DRL, where novel techniques and applications continue to emerge, it is essential to distill the core principles that guide and unite these endeavors. These principles, summarized in the following section, form the bedrock upon which the broader DRL framework is built. By recognizing and understanding these shared foundations, researchers and practitioners can not only appreciate the richness of DRL's possibilities, but also effectively contribute to its advancement and innovation.

3.3 Four Principles of Design Research Labs

The four principles that emerged from this approach should be viewed as coexisting and shedding light on various facets, rather than having a hierarchical relationship.

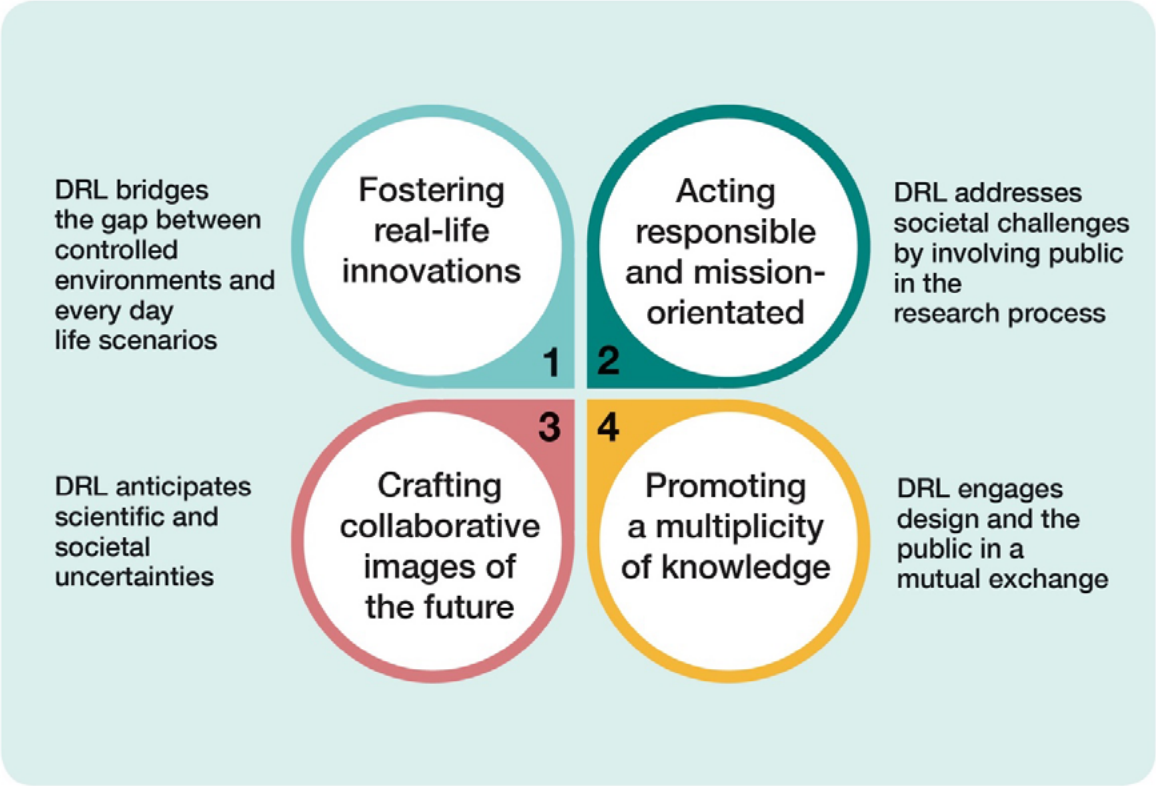

Figure 1. The DRL-framework by the authors (Harles & Augsten), 2023.

1. Principle 1: Fostering real-life innovations

   DRLs metaphorically embrace the concept of scientific labs, characterizing them as controlled environments where knowledge is generated through experimentation and measurement (Binder & Brandt, 2008). Unlike the traditional scientific notion of exclusive access for eligible researchers within an institution, DRLs are seen "as platforms for collaborative inquiry" (Binder & Brandt, 2008, p. 121). It is evident that case studies within DRLs often occur beyond the confines of design faculties' studios and lecture halls. Instead, they are situated where the interventions are intended to be applied. Consequently, the individuals and groups directly affected, as well as strategic relevant collaborators, actively participate in the knowledge production process. What is even more significant is that these activities occur directly in real-life, everyday environments. Prototypical solutions are developed, where they are needed. For instance, considering the case of the Malmö Design: Lab (Binder & Brandt, 2008), employees and managers from one company collaborated directly with external healthcare consultants during on-site sessions at the production factory. This approach ensured that everybody actively participated in the lab, where inquiries regarding healthcare for workers were addressed directly with the workers in their actual work environment.
   Another example by Reynolds-Cuéllar (2020) illustrates how coffee farms can become a DRL, framed as a design course, where design students are relocated geographically to rural Colombia, where they are immersed into the everyday life of coffee farmers to comprehend their routines, needs, and challenges. This served as an essential basis for a co-creation process between students and local communities.

The first principle extracted after analyses is to bridge the gap between controlled environments and everyday life scenarios through the sometimes unforeseen collaboration of various stakeholders. In addition, this exemplifies how DRLs blend the structured, controlled environment of a lab with the realities of the field, creating open and inclusive spaces for collaborative knowledge production.

2. Principle 2: Acting responsible and mission-orientated

DRLs focus on societal issues rather than theoretical aspects of the design discipline. They align their research agendas with specific socially relevant topics like healthcare, mobility, or sustainability (Delft Labs), indigenous sovereignty and human-nature interaction (DESIS Lab, Social Design Lab), digital sovereignty (Design Research Lab UdK) as well as the societal implications of technological innovations, interactions, and interfaces. The goal and motivation of the described examples are to address societal challenges by initiating new paths for knowledge production and socially oriented innovation processes through design. They can be described as mission-oriented, meaning they follow a consensus- and value-oriented research framework like Responsible Research and Innovation (RRI), as proposed by Von Schomburg (2013). The RRI framework encourages researchers, innovators, and organizations to consider the broader societal and ethical implications of their work, actively involving the public and stakeholders throughout the research and innovation process (see also Timmermans et al., 2020). DRLs are inherently aligned with this framework in several ways. First, they aim to foster interdisciplinary collaborations with organizations, governments, scientific institutions, and academia. Second, they aim to engage with diverse audiences, including the public, local communities, marginalized groups, and even non-human entities, incorporating them into the innovation process. Finally, they aim to promote non-academic modes of knowledge as well as methods of knowledge production that are not exclusive to academic research, such as everyday expertise and indigenous knowledge. As a result, DRLs promote a comprehensive and forward-thinking approach to research and innovation, with the objective of ensuring that the outcomes of these activities benefit society, adhere to ethical standards, and contribute to sustainable, long-term developments. As a second principle, we identified that a DRL addresses societal challenges by involving the public, as well as specific and marginalized target groups, in the research process.

3. Principles 3: Crafting collaborative images of the future

Drawing from their mission-oriented approaches, DRLs are notably characterized by their emphasis on uncertainties. These uncertainties stem from the fact that many technological advancements (ex.g. artificial intelligence), but also geopolitical and ecological developments (like wars, pandemics, or biodiversity loss)

often bring about unforeseen transitions or transformations and, consequently, unforeseeable social implications. To ensure that technological potentials are early aligned with societal needs, adapt quickly to an ever-changing world, and that probable long-term consequences are considered, DRLs must anticipate and intertwine technological, societal, and political with ecological trends and project them toward probable future agendas. This necessitates the creation of exploratory spaces where diverse stakeholders can examine future developments while anticipating desirable societal progress, all without immediately providing final short-term solutions.

Within this context, the design discipline holds immense potential in addressing uncertainties and managing “non-knowledge” within interdisciplinary knowledge production processes (Harles &

Heidingsfelder, 2022). These potentials are particularly evident in design-based approaches that evolve from Critical Design, including Design Fiction (Bleecker, 2022), Speculative Design (Auger, 2013; Dunne & Raby, 2013), and Design for Debate (Heidingsfelder et al., 2019). Their shared objective is to extrapolate societal, technological, and ecological developments within everyday scenarios, facilitating mutual knowledge transfer. Through the creation of fictional narratives and tangible "as-if" prototypes such as speculative objects, services, or systems (Wensveen & Matthews, 2014; Boer & Donovan, 2012), these approaches embody potential developments in tangible scenarios for a non-expert audience.

These interventions, often referred to as "speculative enactments" (Elsden et al., 2017), have the power to reveal ambiguities and immerse participants in "as-if" situations to provoke reactions and feedback. By initiating social discussions at an early stage of innovation, DRLs facilitate the negotiation of ideas, needs, and common visions among various stakeholders that are not experts in the field. These future visions are the starting ground for creating fields of action in the present. Consequently, DRLs represent a distinct understanding of design as a critical practice, detached from the market-oriented utility of design thinking. In this way, DRLs function as transition spaces or "hypothetical places" (Binder & Brandt, 2008), where the foundation of the innovation process is not ideas but needs, with results emerging gradually throughout the process.

4. Principle 4: Promoting a multiplicity of knowledge

DRLs enable a novel mode of knowledge production that extends beyond traditional academic knowledge generation, often referred to as "Modes 1 and 2" (Nowotny., 2006). "Mode 1" characterizes the traditional, discipline-specific approach with specialized research and academic discourse, while "Mode 2" represents an interdisciplinary, problem-oriented approach that emphasizes collaboration among diverse experts from different fields (Nowotny et al., 2006). However, design-based knowledge processes, as observed in DRLs, go even further, addressing what is also described in the literature as "Mode 3" (Carayannis et al., 2016; Sandstrom, 2014). This is characterised by highlighting the co-production of knowledge involving a diverse array of actors, including both experts and non-experts. This distinction is a central aspect of DRLs. DRLs serve a dual purpose in knowledge production. Firstly, they encourage knowledge production through design. By creating inclusive spaces for both experts and non-experts, DRLs simplify complex issues through visualizations, tangible experiences, and design-based methods. These methods engage multiple senses and encourage experimentation, allowing participants to transcend verbal and existing knowledge constraints (Heidingsfelder et al., 2019). Moreover, DRLs promote knowledge production by facilitating design-based public engagement. In this capacity, they empower the public and non-expert stakeholders to actively contribute to the innovation process, essentially becoming co-designers. This inclusive approach enables the transfer of various forms of expertise, including general, inclusive, and indigenous knowledge, thus broadening the scope of the innovation process. DRLs effectively extend design methods into areas traditionally outside the purview of designers (Binder, 2008). In this way, DRL introduces an essential peculiar characteristic in which they challenge conventional authorship structures in favor of shared authorship between the lab stakeholders (Binder 2008, p. 121).

In essence, DRLs redefine knowledge production by emphasizing collaboration, inclusivity, and the integration of diverse perspectives, ultimately reshaping traditional scientific outcomes. Thus, DRL engages design and the public in a mutual exchange.

4. Perspectives and Challenges from DRL to Public Innovation Labs

The given examples of DRLs demonstrate that, given various application scenarios, a uniform definition remains elusive. More intriguing than the question “What is a DRL?” is the query “What actually defines a DRL?”. In contrast to traditional scientific research laboratories, DRLs are not understood as static, hermetically sealed, non-public spaces. Instead, they are characterized by a distinctly human dimension in which they operate. In this regard, they represent a significant counter-design while simultaneously meeting the demands for interdisciplinary and socially oriented innovation processes (e.g., Open Science). The framework of DLR (see 3.2) introduces various aspects that may spark how public sector innovation labs can benefit from the DLR framework.

The DRL fosters real-life innovations to bridge the gap between controlled environments and everyday life scenarios. So far, most innovation labs in the public sector have been acting shielded. Opening up to a more human-centered reality would support them in becoming more relevant to the challenges of citizens. Observations highlight a different approach to innovation. DLRs prefer a bottom-up approach to innovation, while in the public sector a rather hierarchical, top-down innovation approach is still distributed. That goes along with the recommendation to open up the innovation process and collaborate with multiple stakeholders to focus on socially relevant issues serving the public interest.

DRL addresses societal challenges by involving the public in the research process to act responsibly and mission-orientated. Instead, most public innovation labs are oriented primarily on the political agenda. Involving multiple stakeholders, and taking their perspectives profoundly, might help to stabilize their contribution to a valuable transformation.

Many public innovation labs have been much closer to implementation than visioning due to governing time frames and horizons. DRLs, on the other hand, design speculative visions of the future that act as examples for discourse, as artefacts for a common understanding, and as spaces of possibility. Understanding this vision as a starting point for action is an offer that DLR can make to innovation labs in the public sector to broaden the degree of exploration and openness to include uncertainties.
The relevance of promoting a multiplicity of knowledge demands for integration of multiple stakeholders and the acceptance of the co-existence of multiple forms of knowledge (cf. Mode 3). This view would provide a new form of openness beyond individual expertise and responsibility.

5. Outlook

In conclusion, this paper presents a framework as a systematic approach for analyzing the potential aspects of structural development, responsible research approaches, and various modes of future-oriented knowledge transfer within the domain of DRLs. However, the gap between theoretical principles and practical implementation highlights the existence of blind spots and challenges that need to be addressed:

To the design discipline:

- Affiliation with Design Schools:
  Being associated with design schools provides structural freedom and political independence for a DRL. However, the accessibility to external stakeholders beyond the discipline should be questioned to involve external stakeholders in the process and recognize their added value.

- Beyond traditional scientific outcome:
  Design-based interventions produce implicit knowledge that is not measurable data in a traditional scientific sense. Furthermore, the data collected from such processes is often not evaluable as quantitative, representative datasets in the traditional sense. Thus, these different forms of knowledge generation also demand new types of research results, approaches to evaluation, and impact measurement.
- Knowledge transfer and science communication of Design Research:
  The need for knowledge transfer and science communication leads to the question of how the added value of design research and the knowledge production processes behind it can be conveyed and transferred to other disciplines. For instance, the natural sciences make their research widely accessible through science communication formats, whereas the specialized discourse in design research often remains confined to the design discipline itself, even when interdisciplinary collaboration occurs.

To the public sector:

- Stakeholder expectation management:
  The lack of knowledge transfer regarding design-based research processes and methodologies can lead to misguided expectations from external stakeholders. The aim of DRL often goes beyond quick ideation and prototypes. They foster societal debates to formulate questions, needs, and collaborative visions to define a strategic and ethical framework. They also take structural, cultural, and legal into question, which leads to more long-term processes that are crucial to upscale and implement outcomes.
- Openness towards implicit knowledge and exploration:
  The most enduring challenge innovation laboratories are facing is based on the inherent conjunction of implicit and explicit knowledge, which in processes of public administration serves as one aspect to determine. Innovation laboratories should take on the role of exploring different questions of measuring, judging, and planning need to be deferred so as not to destroy the innovation capacity before it arises.
- Diverse skill sets and new profiles:
  The public sector is driven by clear structures and linear logic that led to bureaucratic hurdles and a culture that is rarely open to new skill sets and multiple profiles. More flexible structures and higher diversity, as a DLR provides, would unfold the innovation capabilities, and help to overcome the upcoming shortage of skilled workers and the demands of younger generations entering the public sector.

Since the development and establishment of public sector labs is an ongoing process, we propose a two-fold approach: Firstly, it would be intriguing to test the framework by investigating more DRLs (see acknowledgments). Secondly, while in this paper we have approached the public sector from a design perspective, it is worth noting that within the public sector, a scattered pattern of labs has been identified, which would also be of interest for further investigation.

ABSTRACT | The Circular Economy (CE) model considers the life cycle of material goods and examines its journey from cradle to cradle; it tries to put human beings in the same species picture as other living things and focuses on design of materials and systems. The Ellen MacArthur Foundation (EMAF) argues for an industrial economy that is restorative or regenerative by design and aims. Regenerative design requires a multi-disciplinary approach which transcends the disciplines of design only. Despite the use of the terms restoration and regeneration, these have not been readily defined in the context of a circular economy. In this paper we critique the term 'regenerative' from different interdisciplinary perspectives. Interdisciplinarity analyses, synthesises, and harmonises links between disciplines into a coordinated and coherent whole. Regenerative design has acquired different meanings and outcomes in different disciplines. Regenerative design is a key component of heterodox economic models such as the circular economy and doughnut economics which contend that the current orthodox economic model of indefinite linear growth is not compatible with 21st century needs. Regenerative design is proposed as a key tool in meeting the needs of the heterodox economic models. This paper uses case studies to illustrate the different understandings of regenerative design from different disciplinary backgrounds, leading to a unifying definition. This paper argues that regenerative design in context of the Circular Economy is misunderstood and needs clearer definitions that support a genuinely restorative economy, one that will need a new politics, fit for the conditions of the Anthropocene.

1. Introduction

We examine the role of design in shaping governance, business, and innovation by exploring the emergence of designing for alternative economic frameworks through the lens of regenerative design as a design process that aims to repair, recreate, or restore the ecosystems in which it operates and on which it relies. It has been applied mostly in the built environment. The fields of Design and Architecture, conscious of their roles in the creation of demand for and consumption of natural and synthetic resources, have been at the forefront of the call to reimagine how we design our society and how economic systems may be optimised to respond to the climate crisis. In this paper, we incorporate understandings of 'regenerative' from other disciplinary perspectives, such as marine science and computer science. We contend that regenerative design in the context of the Circular Economy is misunderstood and needs clearer definitions and policies that support a genuinely regenerative economy.

Scientific consensus has, unusually, unanimously concluded that the climate is changing and that it is 'unequivocal[ly]' due to human activities affecting every part of the globe at an unprecedented scale (IPCC 2021). The Anthropocene, a concept originating in the Earth Sciences (Crutzen and Stoermer 2000a, 2000b), posits that the impact of human activity on the Earth's systems can be clearly observed and measured in climatic changes, geological findings such as sediments and ice, and a steep decline in biodiversity (58%) in the last four decades which has led scientists to call it the Sixth Extinction (Kolbert, 2014).

The pursuit of scientific knowledge driven by the Enlightenment values of the seventeenth- and eighteenth centuries and the attendant 'improvement' of the social and natural world gave birth to the Industrial Revolution in the Western world and the emergence of design as an instrument of industry and commerce. Whilst Modernity led to a general improvement of (some) human ecosystems, this came at the cost of systematic destruction of human and non-human habitats, decimation of many other species, and decline in the quality of the Earth's ecosystems. The term 'Anthropocene' thus provides a shorthand to describe the planetwide condition of anthropogenic environmental degradation and climate change coupled with the capacity of human societies to effect those changes. We are positing that the Anthropocene has heralded the end of Modernity and its associated focus on progress. The Anthropocene offers the opportunity to reframe the conceptual framework in which we think about what constitutes progress, the economy and design.

The earth's climate is at a critical juncture, with urgent action needed to avert catastrophe on a planetary scale. Yet, commitment to the necessary actions remains elusive, and a clear gap remains between the stated intentions of governments, and the actions that are required to achieve this target. A lack of concrete outcomes from the latest COP 28 meeting of the UNFCC is only the most recent of successive missed opportunities (House of Commons Library, 2024). The ambition of Net Zero targets by many governments, including in the UK (2021), is undoubtedly welcome, but academics, practitioners, and activists concerned with climate change have increasingly concluded that, given the already-degraded state of the environment, sustaining Net Zero is not enough. Instead, we must adopt a regenerative mindset that rethinks how systems, products and services are designed to service and operate a circular economy that not only sustains but replenishes the ecosystems on which it depends: through regenerative doughnut economics (Raworth, 2017).

Regenerative design, then, critiques the concept of Net Zero for lacking ambition to positively contribute to the environment's restoration. Regenerative thinking can avoid some of the risks associated with the rush to embrace Net Zero; risks include centuries of ecological thought, particularly that of indigenous peoples, being disregarded, or that environmentalism is framed simply and exclusively as the technological optimisation of lower-carbon manufacturing, distribution, and servitisation.

Our arguments have been informed by a workshop held in June 2023 (see acknowledgments) that examined the term 'regenerative' in context of regenerative tourism, drawing from different interdisciplinary perspectives spanning ecology, biology, design, literature, craft, computing, business

studies, and tourism. In the rest of this paper, we begin by presenting an overview of the framings which intersect with regenerative design: design theory, critical studies, heterodox economics, and ecology. We critique the circular economy through the examination of the term 'regenerative', expanding its interdisciplinary meanings beyond a design lens only, and go on to describe our proposals for the benefits of regenerative design. These will be descriptions of regenerative design in other disciplinary contexts such as marine ecology and computing. Finally, we end with a provocation that perhaps regenerative design is ultimately an oxymoron: is it possible to design in a truly regenerative way within the constraints of the current economic system?

2. Introduction and Background

What is design? If design is the process of applying creativity to solve problems (Design Council, n.d.) then 'everything not made by nature, has been designed' (Design Council, n.d.). The expansive notion of design as 'design thinking', from product to service design, landscape design to architecture, software and interaction design, was originally framed by Richard Buchanan (1992) where he outlined that the subject matter of design is potentially universal in scope. Buchanan expanded on Horst Rittel's idea of 'wicked problems' (1972), which are 'a class of social system problems which are ill-formulated, where the information is confusing, where there are many clients and decision makers with conflicting values, and where ramifications in the whole system are thoroughly confusing' (Buchanan, 1992, p. 15). For Buchanan, design can be applied as an iterative process to solving 'wicked problems'. Climate change has been defined as a wicked problem (Termeer *et al*, 2013) to which design thinking can be applied to help solve some of its intractable difficulties.

To begin with, *sustainable design* can be situated in a tradition first expressed by Victor Papanek in *Design for the Real World (*1972), which urged designers to take responsibility for the external consequences of their work on users, society, and the environment, rather than see themselves only as service providers to industry, which inherently 'defutures' (Fry, 1999). Sustainable design entailed a 'first do no harm' ethos, arguing that the manifestations of our designed and engineered enterprises should sustain the natural environment that provides the raw materials to realise them, as well as the ecosystems necessary to maintain those environments. The landscape architect John Tillman Lyle (1996) first outlined *regenerative design* for sustainable development. He argued for design to be understood in 'a large and inclusive sense' in the conceiving and shaping of complex systems in which 'the earth and its processes join with human culture and behavior to create form' (1994, p. ix). He argued for a collaborative, interdisciplinary design process that is inherently self-renewing.[1] Lyle was aware that complex multi-goal regenerative systems that involved both natural and social processes, which might not be entirely understood by designers would be challenging for the design process. Lyle outlined strategies for regenerative design:

1. letting nature do the work;
2. considering nature as both model and context;
3. aggregating, not isolating;
4. seeking optimum levels for multiple functions, not the maximum or minimum level for anyone;
5. matching technology to need;
6. using information to replace power (i.e. work smarter, not harder);
7. providing multiple pathways (e.g. not just one source of energy but several renewable options),
8. seeking common solutions to disparate problems;
9. managing storage as a key to sustainability (e.g. storing water, ready for replenishment and release);
10. shaping form to guide flow (e.g. design to support natural air ventilation rather than mechanical one);

[1] In the Center for Regenerative Studies which John T. Lyle ran, the core team of twelve people included two architects, two landscape architects, two agronomists, an anthropologist, an aqua culturist, an energy analyst, a geologist-hydrologist, an agricultural economist as well as two graduate assistants. (Lyle, 1994, p. 31)

11. shaping form to manifest process (e.g. windmills as an integral part of the landscape rather than a hidden infrastructure); and
12. prioritising for sustainability.

The issues Lyle identified arguably qualify as 'wicked problems'. Lyle argued that systems should be designed for optimum levels across multiple functions, rather than one. His regenerative strategies extended beyond Papanek's arguments but have not had the same level of influence on design; in this paper, Lyle's strategies represent some principles on which we build.

Papanek's influential work appeared in the same year as the seminal Limits to Growth (Meadows *et al*. 1972, 1992, 2004) reports which raised profound warnings about the ecological and social limitations of linear growth of the economy. The Meadows reports also contained a message of hope outlining that if humankind could create a society which imposes limits on growth and the production of material goods, then humanity and its interdependent ecosystems of non-humans could achieve a sustainable state and live indefinitely on Earth in a carefully-managed dynamic process of balancing human and non-human flourishing and uses of resources and spaces. Early challenges to the orthodox neoclassical economy that underpinned the indefinite linear growth model, argued for a more devolved, localised and connected economy which supported (local) labour and resources (Boulding, 1966; Schumacher, 1973). More recently, the case for 'prosperity without growth' (Jackson, 2010), 'a new green deal' (Pettifor, 2019), or 'doughnut economics', 'offers a vision of what it means for humanity to thrive in the twenty-first century' (Raworth, 2017).

We suggest that the doughnut economy model, outlined by economist Kate Raworth (Fig. 1), resonates with Lyle's ethos for regenerative design. In the doughnut economy model, the nine planetary boundaries set out by Rockström et al (2009-) form the ecological ceiling which, if crossed, pose a significant risk of irreversible ecological changes. In 2023, six of the nine global boundaries assessed were crossed (Stockholm Resilience Center, 2023). The safe space for humanity is one which is based on a solid social foundation and which operates within the ecological ceilings of our global ecosystems. The doughnut economy model thus provides a framework within which regenerative design makes sense.

However, designing within planetary limits poses significant challenges and requires insights and understandings which go beyond design. To achieve its potential, regenerative design requires a multi-disciplinary approach which transcends the disciplines of design only and requires supportive and integrated policy approaches.

The correlation between financial, social, and environmental sustainability had already been made in the 'triple bottom line' concept (Elkington, 1994) but the circular economy as outlined by the Ellen MacArthur Foundation (n.d.) (EMAF) argues for 'an industrial economy that is restorative or regenerative *by design and aims*'. The concept of the Circular Economy (CE) cannot be attributed to a single author or date (Wautelet, 2018). It describes a closed loop economy, that favours re-use and repair over new goods and delivers positive impact for not only job creation and economic competitiveness but also resource savings and waste prevention (Stahel and Reday-Mulvey, 1981), based on the understanding that there is an extensive

interdependence between the economy and the natural environment (Pearce and Turner, 1990). The CE came to prominence with the publication of a study by the EMAF (2013) with consultancy firm McKinsey at the global economic forum in Davos in 2012 (BBC, 2012), which outlined the significant financial benefit of a CE (Lacy and Rutqvist, 2015; Stahel, 2020).

The CE considers the life cycle of material goods and 'tries to put human beings in the same "species" picture as other living things"'(Braungart and McDonough, 2002); it tends to focus on design of materials and systems. Braungart and McDonough's (2002) 'cradle to cradle' ethos promotes a circular *design* approach that examines the life cycle journey of material goods. The butterfly diagram of the circular economy model (Fig. 2) articulates the 'technical cycle' which involves the management of stocks of finite materials into a circular economy through repair, reuse, redesign, redeployment, and refurbishment. The 'biological' cycle instead focuses on the flow of renewable materials into the generation of nutrients as part of the natural ecosystem.

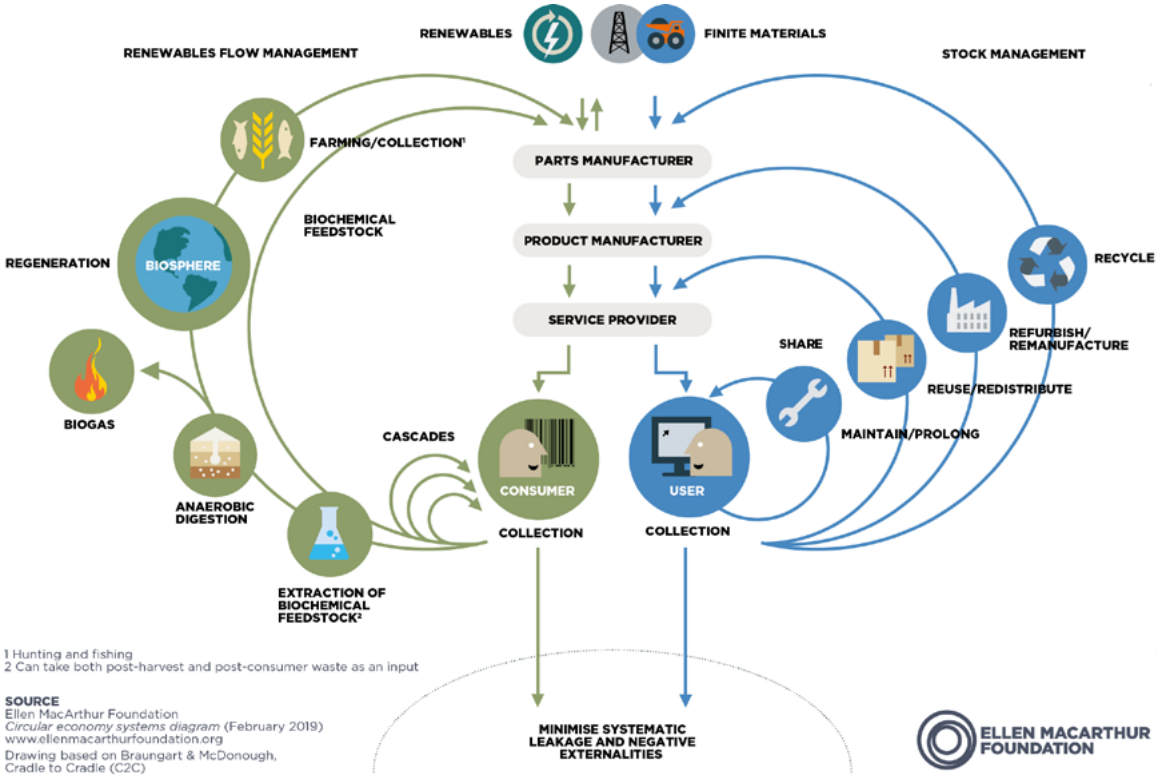

Figure 2. The Circular Economy Butterfly Diagram. Ellen MacArthur Foundation (February 2019) – drawing based on Braungart and McDonough Cradle to Cradle. Source: https://www.ellenmacarthurfoundation.org/circular-economy-diagram.

Critiques of the CE have argued that it does, however, not address ontological and epistemological questions, such as what might be considered the ethical value of design, or what is or who the economy is for? Temesgen et al (2021) posited that the CE foregrounds efficiency and resource management, which they contrast with the paradigm of 'Ecological Economics' where the goal is to achieve and secure a higher quality of life. This arguably aligns with the doughnut economics outlined earlier. Furthermore, the CE tends to fail to acknowledge either the impossibilities of a 'closed loop' in terms of biophysical limitations or the difficulties in implementing CE principles in policy and business models that are dominated by corporate thinking, lack holistic approaches, and ultimately do not challenge the growth agenda of the current capitalist system (Corvellec, Stowell and Johansson, 2021). We will return to this need for a new 'ontopolitics' (Chandler, 2018) in our discussion later on. This 'depoliticization agenda' (Valenzuela and Böhm, 2017) of the CE is challenged in the concept of 'regenerative design'.

The distinction between technological and biological cycles in context of a CE is useful in discussion of regenerative design. Morseletto (2020) argues that most CE activity focuses on *restoration* as products are repaired, upgraded, refurbished, or remanufactured which restores them rather *regenerates* them. As Pawlyn (2019) argues, 'Sustainability hasn't made enough headway to ensure our society persists beyond the middle of the century. We need to start doing more.' Regenerative design therefore aims to create outcomes 'in which whole-system health and wellbeing increase continually' (Gibbons, 2020). In other words, it is no longer enough to do no harm, we must also design to repair the harm we have done. As design relates to both 'technical' – use of technology, equipment, infrastructure etc. – as well as 'biological' cycles – use of natural resources – this framing is helpful to explore the different interpretations of 'regenerative' from different disciplinary perspectives. Despite the use of the terms restoration and regeneration, these have not been readily defined in the context of a circular economy (Morseletto, 2020).

In response to criticisms that design risks accelerating the technological optimisation of carbon manufacturing (business as usual) and ignores other ways of knowing and doing that are more in tune with ecological living, such as indigenous knowledge, design scholars have proposed Responsible Design (Hernandez and Goñi,2020) as a framework for research and practice that is both regenerative and inclusive (Fig.3).

Figure 3. Six Principles of Responsible Design (Boehnert, Sinclair, and Dewberry, 2022).

The Six Principles of Responsible Design (Boehnert, Sinclair, and Dewberry, 2022) are that design should be 1) ethical, 2) pluriversal, 3) planet centric, 4) decolonial, 5) transdisciplinary, and 6) optimistic. Designers can be valuable agents of social change, but, as the Design Council (2021) notes, 'for the most part, designers are not yet using their skills and knowledge to deliberately support the green transition in the way that they should and could'. Responsible Design requires that designers accept '(a) the responsibility to avoid harm, (b) the responsibility to do good, and (c) the responsible governance of the design process' (UAL, 2019). In so doing, it demands that designers engage in transdisciplinary practices, that they avoid proposing discrete, single-issue 'solutions' and instead confront a key aspect of ecological theory, namely the systemic nature of the earth's problems and the efforts necessary to address them. Regenerative approaches recognise that humans are active agents in ecosystems (global and local): a key tenet of the Anthropocene.

3. Case Studies

The three case studies we present are drawn from different disciplinary perspectives. They are collated here to highlight how 'design' is applied in different contexts to encourage restorative and regenerative practices and how these terms have different interpretations for different stakeholders. The first case study is taken from marine science where restoration programmes are designed to support the regeneration of depleted ecosystems. The second case study looks at regenerative design applied within the craft industry but from an ecological restoration perspective. The third case study outlines regenerative design practices applied to robot design. These three disciplines all outline regenerative design but have different understandings of what it means in practice.

3.1 Regenerative Design for Mangrove Restoration

Mangroves support the livelihoods and well-being of millions of coastal inhabitants globally by providing coastal protection, regulating water quality, providing food security, and sequestering large quantities of carbon. They are in short, key ecosystem infrastructures. Mangrove degradation and loss (20-25% globally) has impacted communities and economies worldwide. The successful restoration of these ecosystems has been the result of both failures and successes of restoration projects and these learnings are collated in a 'best practice guidelines for mangrove restoration' by the Global Mangrove alliance (Beeston et al, 2023). Following the earlier description of design as the process of applying creativity to 'everything not made by nature', we argue that the restoration process can be considered a design process which has resulted in restoration guidance documents and tools to design and create the right conditions for mangroves to grow back naturally. If the 'most successful way to restore mangroves is to create the right biophysical and socio-economic conditions' (Beeston et al, 2023, p. 18), then creating those conditions is a process of design.

The key stages in this process are as follows: 1) setting goals and assessing feasibility, 2) project design, 3) engagement and implementation, and 4) monitoring and evaluation.

The guiding principles for successful restoration are summarised in six key core principles:

1. safeguard nature and maximise biodiversity;
2. employ the best information and practices;
3. empower people and their needs;
4. align to the broader context – operate locally and contextually;
5. design for sustainability; and
6. mobilise high-integrity capital.

The principles outlined above support a restoration process that should enable the mangrove ecosystem to look after itself without any further human intervention. The impact of restorative practices on the connections between ecological, social, and economic systems has been evidenced repeatedly and is captured in these guidelines. Getting the hydrology right optimises the chances that the mangrove will not require any more intervention because it will function autonomously in balance.

The ecological restoration here facilitates ecological regeneration. The restoration process in turn supports the reversal of coastal erosion, increased biodiversity, increased natural stock, and thus improved economic benefit. Restoration is defined here as the 'act of bringing an ecosystem back as near as possible, to its original condition' (Beeston et al, 2023, p. 7). It is, however, not always clear or defined what the original condition might have been, in which timeframe, and by whose definition. Ecologists, however, call this process restoration rather than regeneration even if the system has been restored to such a level that it can now repair and sustain itself after having been improved, if degraded, and is in better condition than it was before. Conversely, natural regeneration is defined as 'a process where propagules or seeds of mangrove (or other ecosystem components) are naturally recruited. This may occur in both degraded and non-degraded areas' (p. 6). The differentiation is that restoration has an implied human intervention, and

regeneration has an implied non-human process. All of Lyle's twelve strategies for the *regenerative design* process have clear resonances with the restoration processes outlined in the design methodology of the regeneration of mangroves. In this context, then, regenerative design describes and informs the conscious planning of ecological restoration that takes into account the relationships of ecological, social, and economic systems and leads to self-sustaining ecosystem flourishing.

3.2 Regenerative Design in Crafts Industry

The demise of traditional knowledge and its concomitant social values in the wake of industrialisation and globalisation was observed by the nineteenth-century British industrial designer, social activist, and proponent of the Arts and Craft Movement William Morris (1834–1896) who perceptively noted in 1884 that the globalised market economy affected craftworkers adversely globally. Yet, many indigenous communities retain strong connections with their local environments through artisan products and practices such as textiles, pottery, basketry, and blacksmithing which are made of, and speak of, place. The tensions between producing craft products that attract a global audience and their associated carbon footprint have focused attention on local markets and maintaining local customs and traditions which often encapsulate multi-generational knowledge of materials, habitats, and ecosystems. Truly regenerative design has been most successful where initiatives to restore habitats have incorporated social and material innovations (Watson, 2020; Panneels, 2023).

One such example is the Khoriya ko Kagaj project: the planting of broom grasses on the bare hills of the Mahabharat mountains in central Nepal by the Chepang community to stop erosion.[2] The 'amliso', or broomgrass, is traditionally used to produce 'brooms' for the domestic market and generates income for this marginalised community. As only the flowers are used for the brooms, the stems were a waste product which has now been developed into a higher value product by working closely with traditional paper-making artisans to develop a new, robust handmade paper from this waste material, thereby generating a new income stream. Although the waste produce could be easily absorbed back into biological cycle, here the natural waste is used to create more product that generates income as much as it restores the local ecosystems. The project has thus incentivised the Chepang community to restore the hills with broomgrass, stopping erosion and landslides and creating income streams. The system was designed to thus optimise the restoration of both the ecological habitat and the social community which depends on it. The design process followed several of the twelve principles of regenerative design outlined by Lyle by 1) letting nature do the work, 2) considering nature as both model and context, 3) aggregating, not isolating, 4) seeking optimum levels for multiple functions rather than one, 7) providing multiple pathways, 8) seeking common solutions to disparate problems (erosion and ecological degradation and poor economic prospects) and 12) prioritising for sustainability.

A key argument in sustainable design is to re-connect and re-evaluate traditional knowledge and indigenous ways of knowing which often harness nature's inherent restorative capacities and was recently captured in the phrase 'Lo-TEK' coined by designer Julia Watson, as radical indigenism (2020). She argued for a design movement to reconnect with lesser-known, local (Lo) technologies, both traditional and recent innovations, borne from Traditional Ecological Knowledge (TEK) to design and build climate-resilient infrastructures. This intersection of innovation, conservation, and indigenism, she argues, could offer a new path to 'exponentially shrink the ecological footprint of humankind and mitigate the forecast collapse' (p. 18). Like Lyle, her perspective is from a built environment point of view but, we argue, its principles of design are universal and can also be applied to other sectors of the economy.

[2] This project was supported by the British Council in Nepal through the In Our Hands programme in that supported nature inspired innovation in the creative economy. A short video of the project can be viewed here: https://www.youtube.com/watch?v=_Dmq5OIQYhQ&t=6s.

3.3 Regenerative Design for Robots in a Circular Economy

The CE distinction between technological and biological cycles are critical in the discussion on regenerative design. The previous two case studies have unequivocally engaged with natural ecosystems and their intersections with social ecosystems and economies. In this last case study, we briefly outline the use of regenerative design in the context of a technological cycle: the concept of regenerative design for robots. Robots have often been designed in a linear way: when parts break, they cannot be replaced, and the robot becomes obsolete. A circular design approach would 'fix' the problem by implementing a design approach that enables the repair and replacement of broken or faulty parts until no further repairs can be enacted. All parts are to be designed to be taken apart and recycled into the waste stream. Recent developments have included robots that are able to 'fix themselves' with built-in automated repair functions, mostly driven by the deployment of robots in hostile or inaccessible environments (e.g. deep-sea mining or outer space) where human intervention and repair might not be possible. A second development is that with the increased miniaturisation of robots, existing power infrastructures such as motors and gas engines are no longer serviceable and engineers. Designers have increasingly turned to 'biohybrid' robots which integrate living cells into mechanical bodies, 'benefiting from the intrinsic microscale self-assembly of living tissues and high energy efficiency, which, among other unprecedented properties, also feature flexibility, self-repair, and even multiple degrees of freedom' (Lin et al, 2022). Mini robots have been deployed in search and rescue situations, or in medical procedures, where they can enter the human body to perform noninvasive surgery for example. New research, however, is also exploring how robots might not only be able to use biomimicry (Benyus, 1997), but also combining bioengineering, nanotechnology and 3D bioprinting (Lin et al, 2022), for example bio hydrogels which expand and contract using ultraviolet light to propel a swimming robot (Shi et al in: Lin et al, p. 119). Increasingly biomaterials are being used to develop robots which have a high biocompatibility and biodegradability, which is important in medical situations for example. Thirdly, robot design has now included the use of biomaterial for robots to self-replicate (Kriegman et al, 2021). This approach is considered regenerative design because it enables the robots to maintain themselves autonomously without further demand on scarce resources.

This third example further demonstrates how the principles of regenerative design operate productively in a range of disciplines and industries. Here, too, several key strategies of Lyle's framework for regenerative design can be aligned; 1) letting nature do the work, 2) considering nature as both model and context, 3) aggregating, not isolating, 4) seeking optimum levels for multiple functions, not the maximum or minimum level for anyone, 6) using information to replace power, 8) seeking common solutions to disparate problems, 9) managing storage as a key to sustainability, 10) shaping form to guide flow, 11) shaping form to manifest process, and 12) prioritising for sustainability.

4. Discussion

This paper argues that regenerative design in context of the Circular Economy is misunderstood and needs clearer definitions that support a genuinely restorative economy. If 'regenerative design' is to be a tool for facilitating a truly circular, regenerative economy which restores the ecosystems on which it depends, and which by implication relies on interdisciplinary collaboration, co-operation and understanding, then a universally understood definition of regenerative design needs to be agreed on. As outlined in our case studies, the concept of regenerative design has acquired different disciplinary understandings.

Regenerative design as understood in the context of our case studies enables an ecosystem to look after itself without any further human intervention: mangroves, bare hillsides, or human and robotic bodies. Critically, it also highlights the 'agency' of humans in this process – a very Anthropocenic approach indeed.

The idea of the Anthropocene has particularly highlighted how human ecosystems (economic, social, and political) are irrevocably enmeshed with ecological ecosystems. However, the emergence of critical theory in the twentieth century as a philosophical approach has provided a kaleidoscopic lens of feminism, critical

race theory, post-structuralism, queer theory, and post-colonialism of the kinds needed to shift the conceptual understandings of Modernity and its concomitant drive for human-centred enlightenment and progress towards a more nuanced understanding that makes space for other ways of knowing and doing. Critical theory has refocused attention on alternatives offered by traditional, indigenous, or artisanal approaches, which often preceded industrialization (Haraway, 2008). Modernity and its process of globalisation had profound implications not only for the loss of traditional knowledge and practices but also for the social values they embodied. For the anthropologist Anna Tsing, the Anthropocene makes it possible to realise that Modernity itself is a barrier to living fuller lives:

> "Progress is a forward march, drawing other kinds of time into rhythms. Without that driving beat, we might notice other temporal patterns. Each living thing remakes the world through seasonal pulses of growth, lifetime reproductive patterns, and geographies of expansion. [ ] Instead, agnostic about where we are going, we might look for what has been ignored because it never fit the time line of progress." (Tsing, 2015, p. 21)

These multispecies, pluriversal (Escobar, 2017) insights are needed to respond to the challenges of climate change in the Anthropocene.

Scholars from International Relations have focussed attention on the implications of the Anthropocene on international governance, which commands an 'ontopolitics' (Chandler, 2018): new forms of governing and new conceptual frameworks which are more at home with 'discursive framings of contingency and complexity' (Chandler, 2018, p. 4) that acknowledge that the world is complex and interdependent. The U.N.'s *Our Common Future* – also known as the Brundlandt Report (WCED, 1987) – argued for sustainable development (growth) that 'meets the needs of the present without compromising the ability of future generations to meet their own needs' and called governments, civic society, and businesses to action. The Report laid the groundwork for the Earth Summit in 1992, which led to the establishment of the U.N. Convention on Climate Change (UNFCC), which established the Convention of the Parties (CoP) as the decision-making arm. Despite the early scientific warnings in the 1980s, such as those of NASA chief scientist John Hansen (Kolbert, 2018), it took until the landmark Paris Agreement (UNCC, 2015) at COP21 in 2015 for a first legally binding document with widespread international agreement on the need to reduce emissions to a level that limits global temperature rise to 1.5 degrees (IPCC, 2021, 2023) by 2030, requiring sustained international collaboration and co-operation.

It is clear, however, that several decades of climate policymaking through the U.N. COPs has failed to deliver these goals. Governance will require a new ontopolitics. We argue that this new ontoplitics will require regenerative design to be embedded at all levels of policymaking, funding and innovation strategies, and economic development. Regenerative design has been adopted by establishment organisations such as the Royal Society of Arts, the Royal Institute of British Architects, and the 1851 Commission3 and carries an inherent critique of the concept of Net Zero. As outlined earlier, the Net Zero targets by many governments to stop emissions of greenhouse gases into the atmosphere are hopelessly inadequate. Emissions are currently at record levels but would need to be halved by 2030 (IPCC, 2021) if we are to achieve Net Zero. A circular economy as currently proposed, which has no theoretical energy loss and is biophysically impossible, suggests an improvement on current manufacturing but does not improve the status quo in ecological or social terms. The 'depoliticization agenda' (Valenzuela and Böhm, 2017) of the CE is challenged in the concept of 'regenerative design'.

The case studies we put forward outlined how regenerative design in mangrove restoration has resulted from explicit regeneration policies, whilst the regenerative craft example operated on the fringes of a creative green economy policy, and the regenerative robots emerged from innovation policies. The term 'regenerative' thus needs to be claimed firmly as a more robust terminology to describe design processes

[3] Royal Commission 1851 was established in 1850 to specifically support advanced study and research in science, engineering and design. It established a Fellowship in Regenerative Design to support the research of regenerative design in the built environment. See: https://royalcommission1851.org.

that should be applied to any industry or sector to describe a process that a) supports both environmental and social regeneration, of which the economy is a defacto by-product – thus flipping the CE mode, and b) which explicitly challenges the continued growth model, which is implicit in the CE.

If regenerative design principles are understood to improve the conditions of the ecological, social, and economic conditions in the context of which this is applied, then this is often achieved by applying Nature-based solutions or Biomimicry which require interdisciplinary knowledge. Furthermore, in order to be able to argue that regenerative design principles have been successfully applied, an understanding of what constitutes a baseline from which conditions can be improved needs to be agreed on. It is clear from our discussions with ecologists that knowing the baseline from which to start are not always clear, nor universally agreed on by all stakeholders.

Instead, we must adopt a regenerative mindset that rethinks how systems, products and services are designed to service and operate a regenerative doughnut economics which serves ecosystems rather than economies. It is worth remembering the ancient Greek origin of the word economy where ‘oikos’ refers to ‘house’ and ‘nemein’ refers to ‘manage’.

5. Conclusion

We have argued in this paper that applying genuine restorative design principles in different disciplinary and economic contexts might simply not be possible. It requires us to move beyond ‘business as usual’ and beyond a circular economy which, although aspires to be regenerative, is inherently an oxymoron: a contradiction of terms. In this paper, we suggest that the lens of regenerative design is a useful way of introducing the embodied complexities and interconnected nature that is the wicked problem of climate change, which requires a new ontopolitcs of the Anthropocene. In order to devise policy frameworks that support complexity, and contingency, we suggest that regenerative design frameworks need to be firmed up to support the development of governance structures which can cope with the unpredictability and urgency of the climate crisis. We are suggesting that regenerative design needs to be re-framed and articulated by trans-, inter- and multi-disciplinary teams in the context of the new ontopolitics of the Anthropocene. Regenerative design goes beyond sustainability and seeks instead opportunities for re-imagining society.

KEYWORDS | DESIGN PROCESS, BRICOLAGE, EFFECTUATION, SENSEMAKING

ABSTRACT | In this conceptual article, I propose a new design process model based on bricolage, sensemaking theory, effectual thinking, and Donald Schön's idea of reflective practice. The design process is the most researched topic in design studies, and introducing a new perspective is challenging. As the design paradigm undergoes a shift and the role of the designer transitions from being merely an expert to becoming more of an enabler, it becomes imperative to explore the ways in which designers engage with innovation My experience suggests that rational and linear normative models do not support constructive design thinking through practice. Reflective design process models, on the other hand, may struggle to guide what should be done in each situation. The designer's "superpower," however, lies in incorporating embodied and intuitive expertise into rational innovation activities within an organization. What new insights can sensemaking and effectual thinking bring to normative design thinking? What does a constructive design process look like when removing rational-analytic elements to make room for designer-like intuitive actions? The contribution of the article is to complement those previous perspectives where design and its practices are linked to the pragmatic paradigm. Design can be described as a visually and materially oriented embodied imaginary service that utilizes imperfect information to integrate meanings for the future. The result can be an unpredictable, surprising, and unique concept. A design process that involves stakeholders in innovation progresses through the integration of stakeholders, imagination, action, reflection, and learning towards achieving a common purpose.

1. Introduction

The role of the designer in innovation activities can be summarized as follows: developing new, unexpected solutions, tolerating uncertainty, working based on imperfect information, applying imagination and constructive anticipation to practical problems, and using drawings and other modeling tools in problem-solving (Cross & Clayburn Cross, 1995). Roberts (2023), drawing on Rittel and Webber's (1973) ideas, lists various general problem-solving strategies as follows: competitive, authoritarian, rational-analytical, taming, and collaborative. In addition to these, a design strategy is also possible for approaching wicked problems.

In design research, two ways of doing design stand out: the linear "rational" model prevalent in product development and innovation activities, and the constructive, reflective model based on Donald Schön's (1983) ideas of design as an intuitive, dynamic, and iterative process. The rational model sees design as one phase in a linear process, whereas the reflective model sees design as an active process throughout the entire innovation process. In this article, I start with this binary framework, where on the one end of the spectrum is a positivist-managerialist worldview and another end is a critical-constructionist (Tienari & Meriläinen 2012) worldview (Figure 1). The vertical axis of the figure represents design practice done independently versus collaboratively.

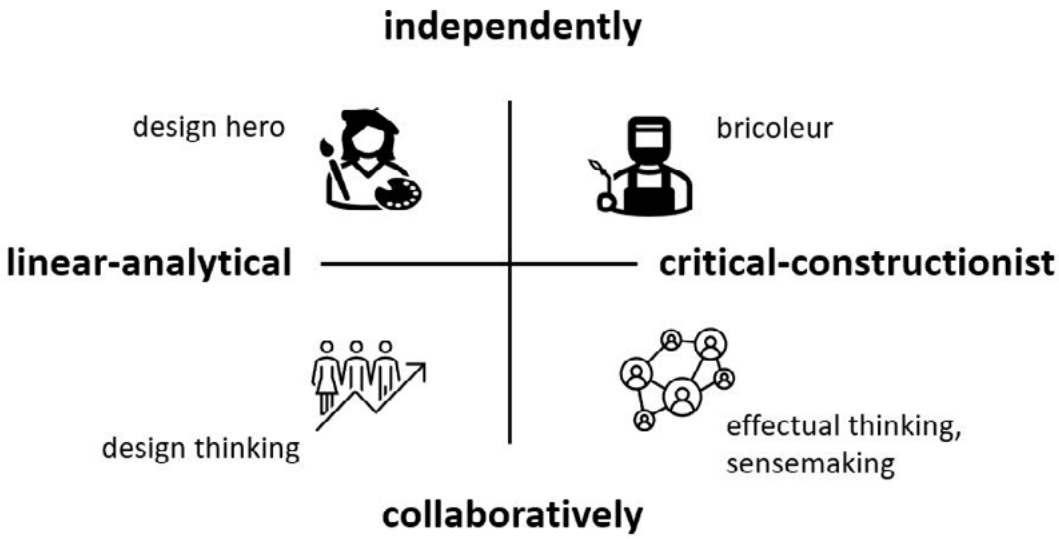

Figure 1. Designer's worldviews: rational-analytical versus critical-constructionist.

My aim with this conceptual article is to contribute to the discourse on the constructionist worldview of design, complementing Schön's reflective perspective with insights from bricolage, sensemaking, and effectuation. This article addresses two questions:

How can design be understood and defined from the perspectives of effectuation and sensemaking?

How can the approach of bricolage, effectuation and sensemaking to design be formulated into a normative process model?

2. Theoretical Framework

2.1 Rational-Analytical Design Thinking

There are dozens of versions of rational models available for the development of new products (look at, for example, Dubberly, 2005). These models typically involve progressing from defining goals and problems to generating alternative solution proposals, then refining and testing them. These normative models are used to guide and manage the creative process in time-bound product development. Interdisciplinary product development teams and novice designers benefit from clear guidance on how to proceed in situations requiring open-ended creativity.

Criticism towards these models has been raised regarding their failure to account for the designer's intuitive thinking or the significance of the social aspect of the design process. Rational models are based on the idea of a predictable future towards which one progresses through consciously planned stages. Over the past decade, the term “design thinking” has gained significant popularity, as it provides an easy way to describe the contribution of designers to product development and innovation activities.

Design thinking is understood to refer to the use of design-oriented approaches in the discourse of business, management, and even social innovation. Books on the subject are often referred to as manuals, toolkits, workbooks, or playbooks, offering how-to guides for design thinking. The term has allowed design or business consultants to capture, commercialize, and trivialize design into a few methods, tools, or process models.

Some design researchers criticize the use of the term “design thinking” to describe this mechanized process, which diminishes the broad knowledge, skills, and expertise of professional designers. Critics argue that mechanical design thinking produces highly conservative thinking and may even make genuine innovation and real change impossible. Thus, design thinking can be seen as belonging to the rational-analytical category, at least in terms of how it is often taught and applied in business settings. Design thinking is just a new name for the old “rational-experimental” approach to problem-solving (Iskander, 2018).

Kimbell (2011) argues that design thinking suffers from several issues: 1) it relies on a dualism between thinking and knowing, as well as acting in the world, 2) generalized design thinking does not depict the diversity of designers' practices, and 3) the designer is seen as the primary agent in design. According to Kimbell, attention should instead be paid to the situated, embodied routines of designers and others.

The activity that occurs in the professional practice of design, in studio work, could be referred to as designerly thinking (Cross, 2023). It is based on thinking through making, intuition, alternating between divergent and convergent thinking, and perhaps empathy. This also includes designerly practices, interventions, interpretations, discourse, as well as linear, artistic, and bricolage-type approaches. Designerly thinking is also not something that can be mastered by reading a workbook, attending a seminar, participating in a one-day workshop, or completing a Design Thinking MOOC course.

2.2 Reflective Design Practice

Donald Schön's (1983) book “The Reflective Practitioner” introduces the design process as reflective action, providing an alternative to rational models. Schön was influenced by the thinking of John Dewey, who argued that habitual action and intellectual reflection occur simultaneously: in competent action, thinking happens precisely within the process, not outside it. The designer creates a situation according to their understanding, and the situation “talks back.” The designer shapes their own environment and must react to it, thus engaging in reflection-in-action. This dialogue often takes place, for example, through sketching and model-building. Action can lead to unintended, even surprising consequences. By reflecting, the designer learns more about the design subject and their own actions, evolving as a designer.

Schön's reflective perspective overlooks the bodily and social dimensions of design activity, including design activities that occur within an innovation-producing organization; the designer often engages in conversation with others simultaneously with the situation. Schön's ideas have also been criticized for presupposing a negative starting point – a problematic situation. However, a designer can act even in the absence of a problem.

The reflective model is descriptive, depicting, and does not instruct novice practitioners on what to do in a situation or how to progress in creative problem-solving. According to the model, one must do something to reflect on their actions. Where does this impulse, this pre-understanding of action, come from?

2.3 Pre-Reflective Thought

Rylander Eklund, Dixon & Wegener (2023) propose – based on the thinking of John Dewey – that pre-reflective thought forms a continuum with reflective thinking (as per Schön's reflection-in-action). Design practice is seen as regular participation in conversations with one's own actions and others, combined with pre-reflective "design artistry." Observation and imagination skills are central here, and the designer develops these skills through sketching and model-making, seeking cues from the environment. Imagination relies on sensations, emotions, and meanings, which together form something new.

The results of observation and imagination cannot be seen in advance, so the designer must immerse themselves in a state of uncertainty, focusing on constructing present meaning through sketching and model-making. Over time, these techniques can be seen to cultivate the designer's "adventurous attitude," where awareness of the environment and sensitivity to impulses grow. Design studio practices, imagination, and improvisation – starting from imitation of more experienced designers – develop the designer's sensibility, which is a key essential skill for the designer (Rylander Eklund, Aguiar & Amacker, 2022).
Designers should not only reflect introspectively but also interact with colleagues. Outward-facing reflection brings together the collective perspectives of collaborating individuals, generating social, political, and emotional material. Parties learn together and form a collective understanding of what is desired (Tan, Kocsis & Burry, 2023). Social practices in studio design shape the collective sensemaking of the parties involved in producing innovation: efforts to build equal peer relationships among stakeholders, openly presenting sketches, facilitating collaborative composition, and continuously narrating the ongoing design process, critically reflecting on the design task given at the beginning of the work (Kettunen, 2014).

2.4 Bricolage

Schön (1983) proposed that architect Quist has constructed a repertoire from examples, images, understandings, and actions encompassing material from various circles of design. It includes places he has seen, buildings he knows, design problems he has encountered, and solutions he has produced. All these are part of his repertoire, insofar as they are available to him for understanding and action. The repertoire is a concept very close to that of the bricoleur's stock of materials.

Bricolage is about tinkering, building, and assembling. It is a concept developed by Lévi-Strauss (2004) for the activity in which a "bricoleur" uses whatever materials are at hand to solve a problem through improvisation. It is an event where the maker wants to express themselves and their identity by using whatever material happens to be available and by creating various signs from different contexts. Materials can be physical, mental images, solution patterns, or social cues.

Louridas (1999, p.522) argues that "design in all its forms is a form of bricolage." Design is not equivalent to bricolage, but we can look at design like bricolage. Weick (2001, p.62) states that designing is synonymous with bricolage, and the designer acts as a bricoleur: "Design is clearly a sensemaking process that gets by using whatever materials are at hand."

The first practical step of the bricoleur in an inspiring project is retrospective. He examines what materials and tools are available before deciding which of them he will utilize to solve the problem. The materials, of course, refer to those he has used previously. The broader their use has been and the more widely they have been understood, the more innovative the bricoleur is in improvising new forms from his stock of materials. He doesn't know the materials because they were useful; rather, the materials are useful because he knows them (Weick, 2001). The bricoleur's thinking diverges from rational logical analysis and planned ways of thinking. The engineer seeks a solution from the universe, while the bricoleur searches for it in his own scrapyard. The engineer dissects and analyzes; the bricoleur reassembles (Louridas, 1999).

A designer becomes a bricoleur when he uses the means at hand to solve a problem, whether these means are concrete in model building or waste pieces or parts of other products found in the corner of the workshop in prototype construction, which have no connection to the product being designed. The designer also operates according to the bricolage model when he draws on his stock for solutions, ideas, and new assemblies. He uses as his stock images, shapes, methods, or solutions from other fields than the one in which he is currently working. The “materials” at the designer's disposal also include the forms he has encountered previously and which he can try to apply to new problems. In this case, the result approaches mannerism, which is a stereotypical, ingrained way of using familiar solutions.

Designers are known to continuously gather material and visual material as a background process for inspiration for new concepts (Keller, Pasman & Stappers, 2006). One conscious method is mood boards; these collections of images serve as stimuli and solution patterns from which the designer can pick parts for their own problem-solving (Baxter, 1995). This strategic skill of the bricoleur – wayfinding – is opposite to the pre-planned navigational strategy (Chia & Holt, 2009).

2.5 Effectual Thinking

Effectuation theory (Reed, S., Sarasvathy, S., Dew, N., Wiltbank, R., & Ohlsson, A-V., 2011; Sarasvathy, 2022), which has emerged in the discourse of entrepreneurship and business studies, also offers a potential perspective on interpreting design events; after all, there are many similarities between entrepreneurship and design. An entrepreneur shapes a company, continuing from where the product designer left off. Like the designer, the entrepreneur is interested in “what could be” (Nielsen & Christensen, 2014).

Managerialist leadership, including design management and partially design thinking, assumes that the future can be anticipated and approaches the future through analysis, strategic planning, and rational reasoning. Effectual thinking often views that the future cannot be predicted but unfolds as a result of our actions. These different logics are like oil and water. The effectual worldview describes the future as malleable and full of unforeseen opportunities, whereas the prevalent causal-rational analytical worldview in many professional contexts focuses on predetermined goals pursued through forecasting and reducing variations (Hanson, 2020). Causal logic considers how to reach the goal or vision. Effectual, or let's say interactive logic, asks what I can do, who I know, and what I want to do, and then begins to do something (see Figure 2). In the process, new parties, partners, who bring in new skills or new goals, come into play. Entrepreneurs do not know in advance where they will end up; they cannot act according to pre-defined strategies. The same applies to the designer who seeks something non-existent. The future is not found; it is made.

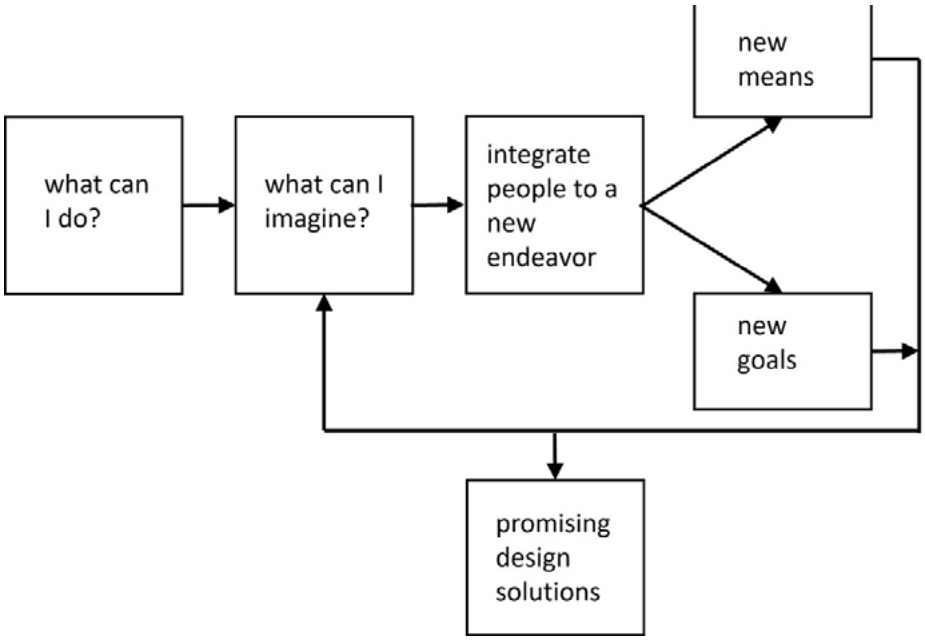

Figure 2. The Effectual Process (adapted from Reed et al. (2011) and Nielsen ja Christensen (2014).

The model (Figure 2) illustrating entrepreneurship, appears familiar to the designer: that's exactly how design progresses. Its logic is guided by the available means and skills, and it materializes if the right people become interested and committed to the presented opportunities. One just has to start from somewhere, and you can't always know where it will lead.

Effectual partnership differs from causal partnership in the belief that those who decide to join the project and choose themselves to be part of it make the project what it is. This sharply contrasts with selecting partners for the project based on how they fit into a given goal. Effectual partnership shapes the project, and the project does not dictate the partnership. Metaphorically, an effectual project is more like a patchwork quilt than a jigsaw puzzle. In a patchwork quilt, there is a broader range of possibilities for solutions, whereas in a jigsaw puzzle, there is only one correct solution. Extensive patchwork projects are communal. Contributors bring their own perspectives, preferences, workflows, and means to the project and must adapt their work to others' contributions.

The willingness of partners/parties to commit to building the process is paramount—not their suitability for a predetermined vision or opportunity. Each participant shapes the vision and brings their own means and tools to its realization.

2.6 Sensemaking

The design process can be examined through the lens of sensemaking, popularized by Karl Weick (1995), to better understand what happens during the design process. Weick's roots of sensemaking lie in his attempts to understand the framework of organization process from a social psychological perspective, which is an alternative to the analytical view where an organization is seen as a rational entity (Helms Mills, 2010).

Sensemaking comes into play when a change in the flow of routines occurs, forcing us to think about what is happening and how we should act. In product design, sensemaking is emphasized, for example, when it becomes apparent that the world has changed so that current products are no longer selling. Now more than ever, the question arises: what is this situation all about and what should we do now?

Sensemaking involves continuous, backward-looking development of plausible images so that the images make sense of what people are doing (Weick, Sutcliffe & Obstfeld, 2005). Sensemaking is ongoing, with no beginning or end, but the efforts of sensemaking become clearer when the current state of the world is

perceived to be different from the assumed state. People break moments from the continuous flow of events and pick up clues from past moments, attempting to make things rationally explainable (Weick, 1995).

Sensemaking is primarily a conversational and narrative-based social process, manifested in negotiations, storytelling, rumors, and gossip (Brown, 2000; Brown, Stacey & Nandhakumar, 2008). Informal discussions serve as arenas for creating meaning, partially reducing the ambiguity that people experience (Engwall & Westling, 2004). Physical cues and signals, such as expressions, gestures, behavior, and actions, also help in making interpretations and assigning meanings (Balogun & Johnson, 2005).

The sensemaking process is a learning process and depends entirely on the learner's collective sum of knowledge, emotions, and past experiences, thus entirely depending on their perspective (Kolko, 2010). Another perspective is organizational sensemaking, a collaborative process in which people attempt to understand the situation and the best way to act in a changing, unclear, and uncertain environment.

Action is essential to sensemaking. Only when we say something out loud do we know what we are thinking. Only when we do something can we understand what it means. According to Weick (1995), we enact our environment productively. Reality appears as a continuous interpretation and updating of our experiences. We crave order, but reality gives us exceptions to prevailing rules, and these exceptions make us reshape our order (Minzberg, Ahlstrand & Lampel, 2009).

Simultaneously, *sense-giving* can affect both the actor and the target audience equally well. “When you hear yourself speaking, you see more clearly what is important and what you had hoped to say” (Weick et al., 2005, p.416). For designers, drawings and prototypes are also tools for sense-giving, albeit in a quite tangible form. The model provides others with the opportunity to create their own meaning, but at the same time, it “sells” the designer's vision. Designers often soften the direct selling of their vision by presenting multiple alternative solutions, allowing others to participate — at least in narrowing down the options.

Rylander Eklund et al. (2022) view sensemaking as the underlying logic of design practice, with improvisation and imagination being core activities of design practice, developing the designer's sensibility. The authors divide philosophical background assumptions into two paradigms: design as problem-solving and designing as sensemaking (Table 1). They depart from rational-analytical thinking about design as problem-solving. As an alternative paradigm, they offer designing as sensemaking, whose pillars are the designer's cultivated sensitivity, imagination, and improvisation.

Table 1. Perspectives on designing. Adapted from Rylander Eklund et al. 2022.

Design as problem solving	**Paradigm**	**Designing as sensemaking**
Cognitivism	Theory	Pragmatism
Deliberate, causal	Practice	Imanginative, improvisational
Cognitive operation	Creativity	Embodied, situated, social
Methods	Pillars	Sensibility
User experience	Empathy	Embodied experience of the designer
Tame chaos	Uncertainty	Embrace chaos
Problem solving as a cognitive act: methods essential	Experimentation	Sensemaking improvisational and imaginative: sensebility essential

Sensemaking begins in chaos, where the situation is unclear and ambiguous. What is this situation? What should we do next? The designer often cannot do anything but immerse themselves in the situation and start acting based on existing premises: sketching and ideating. In these situations, imagination is essential because it gives shape to unknown things, and its necessary modus operandi is improvisation.

3. Design Offering

Design is difficult to define because the perception of it is constantly evolving. Heskett (2002, p.7) proposes the task of design to be "to shape and make our environment in ways without precedent in nature, to serve our needs and give meaning to our lives." However, this generic and human-centered definition does not fully convey what design as an activity can offer to innovation. I submit that there are six major principles of design: it is doubt and imagination-driven, based on incomplete information, is visual and material-making reliant, and future-oriented sensemaking service. Figure 3 summarizes the design offering based on reflective thinking, bricolage, effectual thinking, and sensemaking.

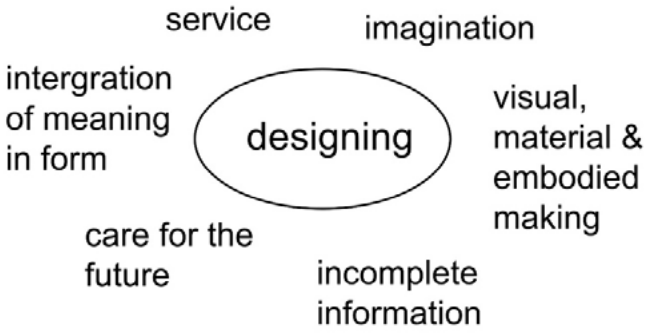

Figure 3. Summary of the design offering based on collective and constructivist worldview. Design is a service that arises from incomplete information, doubt, and imagination, producing sensemaking of the desired future.

3.1 Service

Design can be seen as a cognitive or technical performance, but also as a social activity within an organization. The stakeholders include the client who commissioned the design work, the company's management, marketing, product development, design team, partner and subcontracting companies, and external stakeholders - the end user. The discussion in design often focuses on consumer needs and behavior. However, the customer – the innovation producer – is the most important social contact for the designer. There is no design project without a client who pays the designer's fee and bears the risk of the product's success.

Design activity is a service relationship between the client and the designer. Whereas art and science are self-serving, designers serve others – a broader innovation process (Nelson & Stolterman, 2012). Design service differs from normal service in that it is not about helping the customer by creating something they know they want. The customer may not always fully know what they want from a new product. The designer must address and surpass the customer's often loosely defined goal of the desired outcome: "now that I see this, I know this is what I wanted." It is not about finding meaning in the sense that an idea or concept would await its discoverer or inventor somewhere. The designer cannot ask the customer what this designed outcome would be, but must empathetically ascertain the customer's desires, which focus on the product's utility, form, and technology. The designer's role is to act as a midwife to the original desire, which could not have been imagined in the form realized by either the customer or the designer's individual actions, and deliver a result that is contradictory, unexpected. The outcome is something new to the customer, but they also recognize that it is suitable and useful for their own interests in a specific situation.

3.2 Imagination

Imagination is a basic human capability. When imagining, we bring forth images or concepts that are not real or present to our senses but appear in our mind's eye. The psychologist Lev Vygotsky views imagination as the basis of all creativity and "an important component of absolutely all aspects of cultural life, enabling artistic, scientific, and technical creation alike." (Roberts, 2023, p.129)

Although imagination seems essential to the production of design, it has received little attention in design research. Imagination is often seen as a hidden source of creativity; designers often seek something not yet existing or never-before-seen solutions. The role of knowledge thus comes into the design process: how do we seek the new without simply repeating what already exists. Folkmann (2014) views imagination to be vital in design, as it is in all human thinking and creation. When we imagine, we obtain a visually oriented abstraction that can take us in new directions and lead us to examine new possibilities. Nelson and Stolterman (2012) maintain that in order to create something, one must have the ability to imagine what the something is and how it can be made real. Imagination is required within all fields and all phases of design. Gopnik (2010) suggests that the basis of knowledge lies in a lively imagination. Knowledge and imagination are not separate things. Indeed, imagination, or envisioning possible things alongside real ones, is a precondition for human culture as a whole, not just for artistic creativity and comparable special activities.

Folkmann (2014) suggests that the perspective of imagination can be a useful way to explore the construction of meaning in the design process; and how design objects are positioned, perceived, and conceptualized as tools for creating new meanings. Imagination not only materializes new forms of meaning like products and solutions, but it also reflects and integrates elements of the unknown. Therefore, a key element of the designer's work is to work on the invisible boundaries of the unknown as the designer creates something new and not yet existing.

3.3 Incomplete Information

The designer often has to work based on incomplete background information; it is not always clear *ex-ante* which pieces of information to pay attention to and which not to. The product or service to be designed may not have existed before this moment. Leaders may be unable to envision the future between technological developments and the significance-giving desires of consumers.

The rational-linear approach attempts to acquire and analyze information, anticipate possible futures. This information is fed into a predefined process assumed to generate new innovations. In contrast, the emergent (constructionist) strategy changes along the way; there are always multiple futures, and there is no information about the future, only predictive models. The environment and the actions of customers and competitors cannot be known for certain. Yes, some futures are more certain than others, but as a general rule, the more certain a future is, the less potential it offers for innovation (Compo, 2021).

The rational-linear approach seeks to analyze and define the problem and the goal as precisely as possible. This may succeed in taming problems, but according to Rittel and Webber (1973), for wicked problems, a definition is impossible: there is no stopping rule, all problems are unique, problems are the symptoms of other problems, the description of the problem defines the solution, etc.

On the other hand, as Sarasvathy (2022) suggests, the effectual problem space consists of at least three elements: 1) goal ambiguity - preferences are not given or well-organized; 2) it is not clear which environmental elements to pay attention to and which to ignore, and 3) calculating the probabilities of future consequences is impossible.

The effectual approach relies on the belief that a possible path will be found along the way; the most important thing is just to get started; there is no need for prediction, doing itself becomes the strategy.

Designers work on the things they can control. Goals may not be clear, but values, tastes, and preferences can all be means that guide action. Goals are not committed too rigidly. Design does not try to adapt to the existing environment; instead, committed parties create the environment themselves. This means that in concrete commitments with reasonable risk, the information that emerges is more important than previous background knowledge or feedback received. (Sarasvathy, 2022.)

3.4 Visual, Material, and Embodied Making

The designer's "superpower" in producing knowledge and material change is continuous, embodied, improvisational, visual, material, and social making – thinking through doing (Ingold, 2013; Nielsen & Stolterman, 2012; Bergen, 2009). Designers are makers; they sketch and build, giving form to ideas as solutions. They take that faint glimmer of possibility and make it visible and real to others. The designer sketches and builds models, ideates through bodystorming, and experiments with prototypes and service paths themselves. They display their sketches in the corridors of the workspace for everyone to see and can facilitate participatory, hands-on workshops for representatives from various parts of the organization. According to Krippendorf (2006), 80% of a designer's work is preparing and delivering various presentations. The designer also constructs their own workspace as part of their creative environment; space is a tool for sensemaking (Kettunen, 2014).

The brain operates in our bodies; movements, senses, and social interaction are crucial. The brain always seeks to predict the future, based on the past, it seeks a predictive coding model, forward-looking. Hari & Kujala (2009) talk about the action loop, where the brain in the body affects the world through motor skills, we receive sensory information, and action produces new information. Movement, motor skills, and doing is the driving force of everything. The senses are in the service of action. Knowledge is conveyed through movements. Motor skills are essential in human thinking, like sound and speech; insight requires motor action.

Design processes include embodied knowledge even in the cognitive and immaterial stage of creating mental images of the intended physical designs. Making may be seen as a way of negotiating meaning through interaction between the embodied mind and the material environment, thus it may affect intrapersonal growth and provide a useful platform in educational settings (Growth, 2017). The above sounds like Karl Weick's (1995) sensemaking theory, in which he says: "Only when I have said it do I know what I am thinking." In design, it would mean: only when I have built a model do I know what I am doing.

3.5 Care for the Future

Design is a future-oriented, purposeful activity, a conscious effort to seek the new. When a product or service designed by a designer is launched on the market, the designer has already moved on to the next product to be launched in the future. Instead of examining what is, the designer examines what could and should be.

The designer's initial visualization of the future may be a mood board, reflecting the desired style, quality, and user experience of the product under development. As the name suggests, with a mood board, the designer seeks to create and present a coherent image of the desired direction in which the development could lead.

An ethical attitude can easily be associated with the work of a designer, so in addition to asking themselves whether design provides a solution to human needs, whether it can make money, or whether it is economically feasible to produce, they should also, according to Wendt (2016), ask themselves: "Does this contribute to a future that promotes a positive existence for humans and their environment?" If not, perhaps it should not be designed (see also Roberts, 2023, p.267).

3.6 Integration of Meaning in Form

The designer integrates and creates the first visualization of the desired future. The designer then makes and gives sense. Of course, each participating person understands the visualization, model, or prototype through their own perspective and goals, thus differently, but the designer's concept can be the first concrete, non-textual expression, action towards the realization of the new. Nelson and Stolterman (2012) speak of the concept of desiderata (i.e., desires) as an inclusive whole, combining three approaches: aesthetics, ethics, and reason for that-which-is-desired.

Lee (2023) talks about the designer's role in our post-digital era as an enabler. Thus, the designer becomes an integrator, who in the stages of the design process seeks to consider different parties to ensure the progress of the project. Designers are integrators, "responsible for piloting company activities and identifying new potential segments" (Borja de Mozota, 2003, p.124).

4. Design Process

The designer's task shifts from offering a 'perfectly' finished product to becoming an enabler, continuous facilitator of incomplete possibilities and sensemaking (Borja de Mozota, 2020; Mortati, 2022; Lee, 2023). Rylander Eklund et al. (2023) call for the designer's sensitivity, which develops through the training of imagination and improvisation. Tan, Kocsis & Burry (2023) complement Schön's (1983) reflective idea with a pre-reflective 'designerly artfulness' or 'adventurous attitude', which helps the designer to become more attuned and observant to reality. The abductive process of design is triggered by an embodied experience of doubt, fueled by imagination (Misak, 2004; Rylander Eklund et al., 2023).

The proposed *Sense of Possible* model (Figure 4) has drawn influences from Kolb's (2015) *Experiential learning theory*, which describes how individuals learn by doing through four scenarios: active experimentation, concrete experience, reflective observation, and abstract conceptualization.

Somewhat surprisingly, Figure 4 resembles Resnick's (2018) model of the "*kindergarten approach to learning*," which is characterized by a spiraling cycle of imagine, create, play, share, reflect, and back to imagine. Resnick's model contains almost identical elements.

The Figure 4 model also takes cues from Tan et al. (2023, 8) reflection cycle for designers. Both it and Kolb's experiential learning theory cycle are divided into two phases: designing phase and reflecting phase. This article's contribution is to complement the previously mentioned descriptive models with a bit more normative form and to link the phases of design and reflection to the perspectives of effectual action and sensemaking.

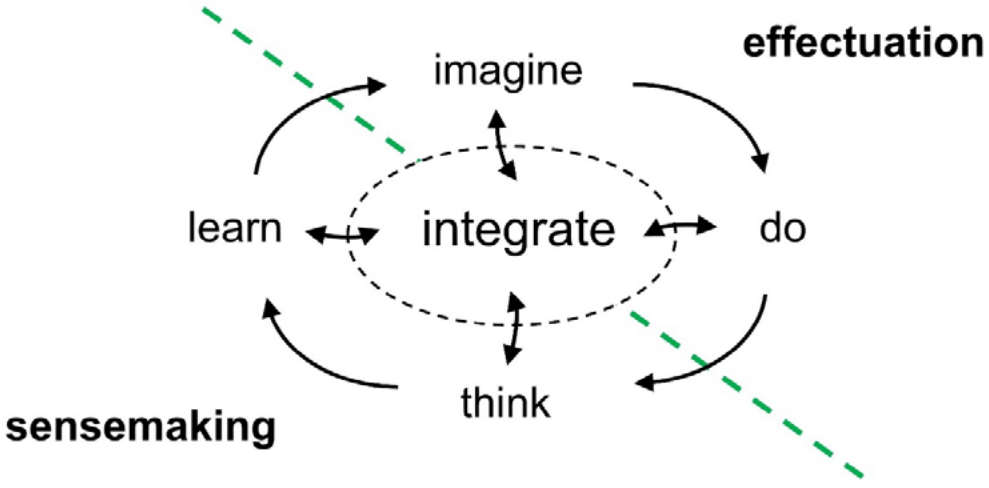

Figure 4. Sense of possible: the design process model based on effectuation and sensemaking.

4.1 Integrate

Design is fundamentally a social process (Bucciarelli, 1994). During the process, designers often perceive their work as both an outcome and a social interaction (Lufti, 2023). Designers are often seen as individuals within organizations who strive to seek, distil, and visualize what kind of innovation is desired. The social sensemaking practices in design, though, manifest in the continuous seeking of peers' input, presenting sketches, engaging others in design activities, and ongoing storytelling – focusing not solely on the outcome, but on the shared process leading up to the present and the near future (Kettunen, 2014). Designers integrate stakeholders to ensure the progression of the innovation process.

The myth of the solitary genius designer persists, but in practice, today's products or services are designed by teams rather than individuals. Designers interact with many people throughout the design process. These may include individuals close to the organization, such as customers, users, subcontractors, etc. Decisions about the direction of design are not made in a vacuum but rather within a social context.

A product that a designer creates exists only in relation to people. A product becomes real only when it is seen, used, interpreted, and owned by people. Designers must consider multiple stakeholders and collaborate with people from different professions. They need to become skilled negotiators who, perhaps through their visual expertise, naturally act as mediators between different perspectives.

Equality among project stakeholders – or at least the temporary illusion of it – is a necessary starting point for opening up and exploiting opportunities. As a designer, innovator, and entrepreneur, you must create opportunities for fruitful collaboration between your clients and various stakeholders. Innovation and business building are social processes; involving another person in the process is essential, as it is difficult to accomplish anything alone. New committed partners bring new means or new goals; you may end up somewhere you didn't know you were going.

Others often have a different way of understanding the situation or problem at hand. They bring not only their own knowledge but also their perspectives, assumptions, goals, and ambitions, making opportunity recognition, process of negotiation and consensus among parties.

4.2 Imagine

The design process can begin with doubt, criticism, and imagination. This entails a pre-reflective artistic design attitude, abductive reasoning, enthusiasm, and an adventurous approach, which materializes as thumbnail sketches and rough models or prototypes. The designer does not seek the right solution to the problem but may develop multiple viable solutions and pathways simultaneously. It can be said that the heart of design is the need to mobilize collaboration and imagination (Telier, 2011).

4.3 Do

Through making – sketches, models, and prototypes – the designer can now reflect (Schön, 1983) on their own actions and their outcomes, and invite stakeholders – colleagues, clients, etc. – to participate in making and reflecting. During the process of making, the designer simultaneously experiments and experiences the design action. Experimentation occurs when the designer makes a move in the situation, whereas experiencing happens when the designer understands how the situation has changed as a result of their actions. Reflection-in-action is iterative (Tan, Kocsis & Burry, 2023).

4.4 Think

Thinking occurs when the designer takes a step back from the situation to observe and reflect on their own actions. Sensemaking emphasizes reflection *on* design action (Schön, 1983) rather than the actual act of designing. At this stage, the designer thinks not only about the design of the product but also about their own design process, reflection-on-design-action. The outcome and the significance of the process (sensemaking) are always constructed retrospectively.

This stage must be distinguished from the previous two stages to avoid “analysis paralysis” (Tan, Kocsis & Burry, 2023). While engaging in design – intuitively, bodily, improvisationally, and imaginatively – the designer cannot critically evaluate their own outcome and actions because the delicate creative process may be stifled by analysis.

4.5 Learn

In this reflection-in-practice stage, the designer takes a further step back and considers how to shape their entire practice critically and conceptualizes a different approach for future design projects (Tan, Kocsis & Burry, 2023). If the designer does not learn from their own actions, if they do not change themselves and their actions through their reflection and thinking, they will end up repeating their mannerisms or mistakes – perhaps successfully – in the next project.

5. Discussion

My goal with this conceptual article is to introduce the discussion of design's constructive worldview, complementing Schön's reflective view with the dimensions of sensemaking and effectuation. How can design be understood and defined from the perspectives of effectuation and sensemaking, and how can the theoretical lens of effectuation and sensemaking be used to formulate design into a normative process model? However, this goal was not fully achieved. The presented model (Figure 4) is not a comprehensive normative guideline on how designers should proceed, but rather an encouragement for intuitive, artistic design action and justification for a designerly way of doing to other stakeholders.

Tan, Kocsis, and Burry (2023) proposed a reflection cycle model for individual designers, while Kolb (2014) introduced the experiential learning theory cycle. Both models consist of two distinct phases: the designing phase and the reflecting phase. This article aims to enhance these descriptive models by introducing a more normative framework and by connecting the stages of design and reflection to the perspectives of effectual action and sensemaking.

Effectuation is more a thought and decision-making process than a method, and its primary purpose is to help explain how truly entrepreneurial thinkers make decisions and create value in highly uncertain environments (Duening et al., 2012). Effectuation also fits well with describing a designer's action in a common situation where initial data and customer desires are not yet clear. Design thinking practices bring the cognitive principles of effectuation to life, it adds a normative dimension to effectual decision-making, as claimed by (Klenner et al., 2022).

The sensemaking aspect of the model depicts the desirable integration of shared meaning – the emergence of desiderata – among different parties with the designer acting as an enabler and integrator. The designers or the innovation-producing organization must step back and reflect on their actions and practices to ensure the success of their innovation endeavors.

Entrepreneurs and designers immerse themselves in situations where they must create shared meaning before they know the criteria for decision making (Weick, 2004). This is akin to the phenomenon known in design research as “intuitive reasoning” (Friedman, 2003). The design profession can be significant because

it has ways to address challenges that are not just technical but also social and creative. Design can complement and bring added value to the efficiency-driven rationality of economists and engineers. Perhaps design can rise to the role it has always wanted to play, building bridges between technological research, economics, ethical and sociocultural responsibilities, and new innovations.

KEYWORDS | DESIGN FOR ENVIRONMENTAL SUSTAINABILITY, IMPLEMENTATION, CHALLENGES, COMPANIES, PRODUCT DESIGN

ABSTRACT | In the quest for sustainable production and consumption and the shift towards an alternative economic framework, design emerges as a crucial actor. Design discipline significantly influences the creation of products, services, and businesses. This study explores the adoption of environmental sustainability and circular economy principles in product design companies, examining the application of strategies, methods, and tools. Through a recent semi-systematic literature review spanning 2018-2023, this research analyses the practical challenges design firms face in the real world. Interviews with six Italian professionals from five product design companies were also integrated, presenting an overview of current applied practices, emphasising the gap and similarities between academic theories and industrial implementations. This paper concludes by suggesting actions and possible directions to design for low environmental impact, drawn from contemporary literature and practitioners' experience. Furthermore, this work calls for design research efforts to be more connected to applicable design practices, be monitorable over time, and tackle significant advances concerning a transition towards sustainability.

1. Introduction

As an evolving field, design is increasingly acknowledged for its potential to drive the transition towards more sustainable economic models (Ceschin & Gaziulusoy, 2019; Moreno et al., 2016). In the last decade, design integration into business configuration and innovation has been recognised as a strategic way to achieve and maintain a competitive advantage (Brown, 2012; Design Council, 2011; Martin, 2009). Today, the role of design goes beyond problem-solving and product innovation. The design practice is progressively seen as a catalyst for sustainable solutions ranging from material and artefact creation to positively influencing sociotechnical systems (Ceschin & Gaziulusoy, 2019). Furthermore, the ability of design to guide companies in aligning with government policies and adopting the circular economy paradigm is an area of active exploration.

In product development firms, design is primarily recognised for decision-making that defines the characteristics of the artefacts. The product design decisions, which encompass material selection, form, and processes, profoundly influence user experiences and behaviours and, significantly, the environmental impact of products. Public sources like the Ellen MacArthur Foundation (EMF, 2013) and the European Commission (EC, 2022) often remark that 80% of a product's environmental impact is determined by choices made in the design phase. As a result, designers, academics, and governments have been developing approaches to implement environmental requirements in the product development process (Ambrosio & Vezzoli, 2019; EC, 2005, 2009; UNEP, 2006). Furthermore, directives and consumer awareness push for design solutions that adopt approaches and strategies that reduce environmental impact (Delmas & Burbano, 2011) and align with the circular economy.

There is a growing interest and development of methodologies, frameworks, and tools created to align industrial product design with sustainability (Rossi et al., 2016). These approaches are widely discussed in academia and scientific literature (Clark et al., 2009; Vezzoli & Sciama, 2006; Vezzoli, 2018); however, they still pose several challenges in practical implementation for corporations and entrepreneurs.

Our study provides an overview of design approaches for environmental sustainability, here intended as Design for Sustainability (DfS) (Vezzoli, 2018), and their practical rolling-out to inform the challenges faced by product design firms in their implementation. We combine a contemporary semi-systematic literature review (from 2018-2023) with insights from five product design companies. This dual perspective enables an in-depth exploration, unfolding reflections on the real-world effectiveness of academic concepts. As a result, we highlight the practical aspects and limitations of design approaches for sustainability and circularity, fostering reflections for developing and implementing new practices that can overcome these limits. We aim to identify and share DfS approaches used in companies and the causes that limit their implementation, offering insights into new directions and bridging the gap between theory and practice.

The study is guided by two research questions: What is the current situation of product design firms in implementing environmental sustainability practices? and What are the practical limitations of applying the theoretical approaches (related strategies, methods, and tools) in business contexts?

The remainder of this paper is structured as follows: Section 2 provides the groundwork for our study. Section 3 describes our methodological approach. Section 4 presents the results and discussion suggesting new directions. Section 5 concludes the paper, summarising the research and limitations.

2. Theoretical Foundations

The earnest attempt to support companies in implementing environmental requirements in product and service design is increasing (Rocha et al., 2019). This tendency has been augmented by consumer awareness (Testa et al., 2021) and stringent global legislative reforms (Shahbazpour & Seidel, 2006). This phenomenon calls for a closer examination of the relationship between business models and product and service design, as they are inevitably linked to production and consumption.

Integrating environmental and social factors into design criteria now stands alongside traditional considerations like profitability, functionality, aesthetics, and ergonomics (Gaziulusoy, 2015). Although the discussion on DfS is not new, the current context requires more than ever solutions towards a future that preserves the Earth's systemic stability (Richardson et al., 2023).

For several decades, environmental sustainability in design has been considered a critical issue (Papanek, 1971). The 1980s saw the introduction of green design concepts in product design firms, paralleling a rise in public ecological awareness. At the product level, these interventions were desired to mitigate the environmental impact of individual products (Madge, 1997). From the 1990s, the focus shifted to designing products with minimal environmental impact. This perspective started to be commonly recognised as Design for Environment (DfE), Ecodesign, product Life Cycle Design (LCD), or product Design for Environmental Sustainability (Manzini & Vezzoli, 2003; Sarkis, 1998; Sun et al., 2003; C. Vezzoli, 2014; C. Vezzoli & Sciama, 2006). These perspectives evolved by broadening the scope to more social approaches, and Design for Sustainability emerged. DfS start to gain popularity, encompassing the social component with the expectation of significantly advancing sustainable development (UNEP, 2006).

Although DfS adopts social factors, these strategies gained recognition from companies seeking to reduce the environmental impact of their products while considering the broad perspective of sustainability. In this regard, the early 2000s saw a popularisation of philosophies for designing products with low environmental impact (Rossi et al., 2016). These approaches intend to guide the design process through associated strategies, methods, and tools. The European Commission directives (EC, 2005, 2009) reinforced these concepts, targeting manufacturers of energy-related products to promote energy efficiency and reduce consumption. Following this, directives and international standards like ISO 14006 (ISO, 2011) were aligned to ensure global best practices in sustainable product life cycle management.

Recently, the European Commission launched a proposal called Ecodesign for Sustainable Products Regulation (ESPR) (EC, 2022), representing a notable progression towards sustainable and circular product designs. This regulation redefines product design to align with ecodesign principles and the Circular Economy (CE) (EMC, 2013). The CE model minimises resource extraction and maintains resource value within the system for as long as possible (Suárez-Eiroa et al., 2019). The CE promotes design practices focusing on durability, reparability, and resource efficiency. This model encourages firms to embed Circular Design (CD) into their development processes. In this context, CD can be defined as creating products focusing on material cycles and the intended business model to ensure sustainability and resource efficiency (Moreno et al., 2016).

Under the CE framework, CD has been established to protect economic and environmental values by moving away from the take-make-waste model (EMF, 2013). At the same time, ecodesign or DfS (focus on ecological requirements) encompasses a spectrum of activities that aim to reduce the impact of products (and services) to facilitate the transition to sustainable production (Vezzoli, 2018). Even if DfS has a more robust background and CD in business is in its early stages, this study considers both valid approaches to support companies in transitioning towards low environmental impact design.

3. Methodological Approach

To comprehensively understand the implementation and limits of DfS and CD in product design firms, this study adopts a dual-method approach, combining (a) a semi-systematic literature review (SSLR) complemented by (b) semi-structured interviews. A gap was identified in the literature, where structured theoretical frameworks were found, but there was also a lack of detailed information on how companies apply these theories in practice and their challenges. To bridge this gap, interviews with practitioners were conducted to directly explore the real-world application of sustainability practices. Prioritising peer-reviewed literature ensured academic rigour and established a solid theoretical foundation in environmental sustainability within product design. Although industry reports offer insights into current practices, their varied methodologies and transparency levels could introduce inconsistencies in the theoretical basis of this research. Semi-structured interviews were chosen to capture the practical applications of theoretical approaches, aiming to gather qualitative insights not typically available in public or academic reports.

3.1 Preliminary Studies and the SSLR

Preliminary desk research was performed using secondary data to analyse the general ground (Verschuren & Doorewaard, 2010). Literature databases and online sustainability reports from product design companies were considered to map the interest and efforts on low environmental impact. This information provided a conceptual background for the study. However, a lack of information about the current challenges of theoretical frameworks was found in this process, driving the formulation of research questions (Jeyaraj, 2023). The following inquiries motivate the study: (1) What is the current situation of product design firms in implementing environmental sustainability practices? (2) What are the practical limitations of the theoretical approaches (related strategies, methods, and tools) in real business contexts?

For a more systematic understanding, ensuring consistency to the study's scope, a SSLR, as described by Snyder (2019), was undertaken. This qualitative approach began with a selection of keywords derived from the preliminary desk research and motivated by the research questions.

Database and Search Syntax

The keywords were combined using Boolean operators to create strings and conduct the SSLR process. The selected databases were Scopus, ScienceDirect, and Google Scholar, which were chosen for their comprehensive coverage of academic research. The timeframe for the search was deliberately set from 2018 to 2023 to encompass recent literature. The process was finally conducted between November and December 2023. Only peer-reviewed documents were searched, given their academic rigour. Limit source types were articles, reviews, and conference papers. Furthermore, English language publications were selected to ensure the accessibility of the literature.

Titles, abstracts, and keywords of documents were the target. The search terms were tailored to each database's unique syntax and search capabilities. For Scopus, one string was used. In ScienceDirect, two variations were tested for effectiveness. In the case of Google Scholar, the search was restricted to review articles to exclude non-peer-reviewed material such as books or student theses, which may not meet the scholarly criteria required for this study. A global search was conducted to capture diverse, worldwide practices. Table 1 presents the tailored keywords and search strings for each database.

Table 1. String used for each database.

String	Database
(("compan*" OR "firm*" OR "SMEs") AND ("product design") AND ("ecodesign*" OR "circular*" OR "sustainab*") AND ("challenges" OR "barriers" OR "implementation") AND ("strategies" OR "tools" OR "methods"))	Scopus
("company" OR "SMEs") AND ("product design") AND ("eco-design" OR "sustainable") AND ("challenges" OR "barriers") AND ("tools" OR "methods")	ScienceDirect
("company" OR "SMEs") AND ("product design") AND ("eco-design" OR "sustainable") AND ("challenges" OR "barriers") AND ("tools" OR "methods")	
intitle: (("company" OR "companies") AND ("product design") AND ("sustainable design" OR "ecodesign") AND ("challenges" OR "barriers" OR "implementation") AND ("strategies" OR "tools" OR "methods"))	Google Scholars

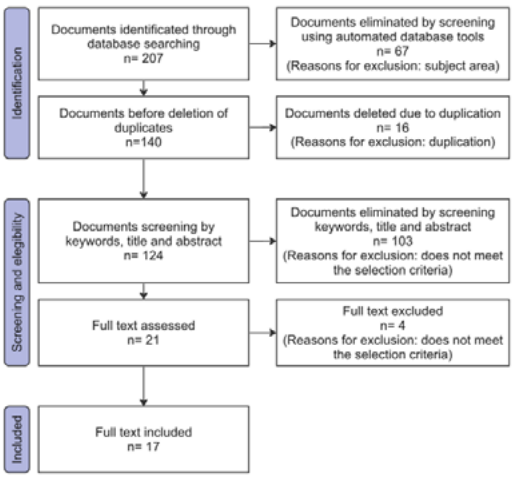
Selection Criteria

The databases yielded varying articles. They were refined by excluding irrelevant subject areas and using the available automatic filters. The focus was explicitly on physical products within various product design sectors, excluding digital-only products. One hundred forty documents were imported into Zotero to speed up the process. Initially, duplicates were removed. The documents were skimmed by titles, keywords, and abstracts, with those considered outside the scope immediately discarded. This process prioritised studies involving tangible products across diverse yet interconnected domains, such as consumer goods, industrial equipment, and furniture.

The remaining articles were assessed against selection criteria, focusing on:

- Design for environmental sustainability approaches and/or circular practices in product design firms (or real-world projects) enhancing low-impact solutions;
- At least one approach to environmental sustainability or circular practice implementation in product design real-world;
- Specific challenges or barriers in adopting sustainable and circular design approaches;
- The gap between theories and practical implementation.

A more thorough examination of abstracts and keywords further narrowed the final selection of articles for a full review. The selection process is illustrated following a PRISMA flow diagram (*PRISMA*, 2020)



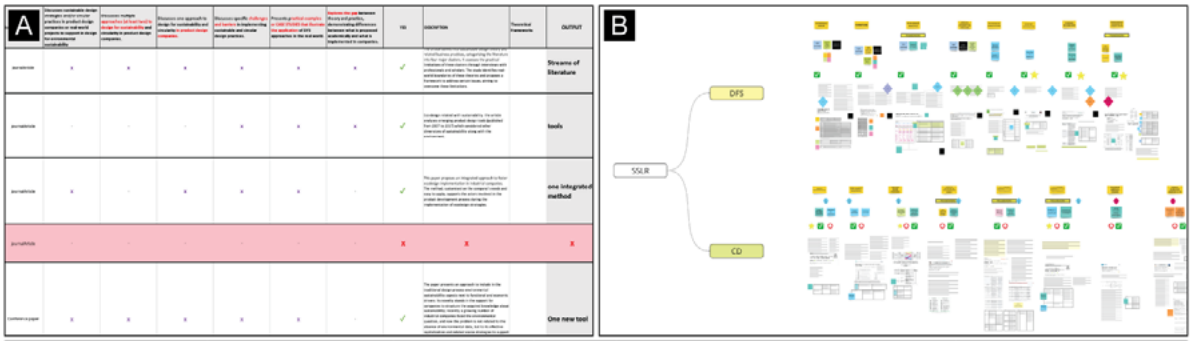


Figure 1. PRISMA flow diagram adapted for this research.

Content analysis was employed to synthesise the collected data outlined by Duriau et al. (2007). Excel spreadsheets and Miro boards were used to catalogue the documents and construct mind maps, aiding in the reflection and categorisation of the findings. Colour coding enabled a more systematic identification and reporting of patterns.

3.2 Semi-Structured Interviews

After collecting insights from the SSLR, semi-structured interviews were conducted to gain a profound and real-world understanding of the issue under study. As Adams (2015) described, this method allows for an in-depth exploration of professional experiences, opinions, and knowledge. These interviews aimed to uncover details outside of the literature. As Gugiu and Rodríguez-Campos (2007) indicated, an interview protocol was designed to guide the data collection and increase the reliability of the study.

The selection criteria for companies were highly pragmatic. Although they do not represent the whole sector or a worldview, they constitute a relevant sample for the study. Firms with proven readiness and consent to share in-depth information about their sustainability efforts in design, challenges, and achievements were selected. Furthermore, the geographical location was essential to allow fast communication and the possibility of face-to-face follow-up meetings.

Interviews were programmed remotely via video conference software to accommodate participants' locations and schedules. The interviews were carried out during December 2023 and February 2024. Each session lasted approximately 50 minutes and was audio-recorded with participants' consent. Transcription, coding, and thematic analysis were conducted to identify patterns and results.

4. Results and Discussion

4.1 General Analysis

Seventeen documents met the eligibility criteria. Each contributes to the discourse on low environmental impact practices in product design companies. The selected documents illustrate approaches, their implementation in practice and the challenges of their adoption. A direct discussion of the theory-practice gap is not uniformly presented. Nevertheless, the complexity of applying theory in practical settings is a recurring theme in all contributions. Table 2 illustrates an overview of the result of the selected literature, highlighting the research method, outcome, and lens.

We divided the literature selected between studies under the lens of circularity, with nine results and those over environmental sustainability, with eight results. This parity suggests that both concepts are acquiring equivalent attention among companies in the discourse on designing with a reduced environmental impact.

Table 2. Overview of the literature included in the semi-systematic review.

Reference	Research approach	Outcome	Lens	
			Circularity	Sustainability
(Ahmad et al., 2018)	Literature review	Classification scheme		x

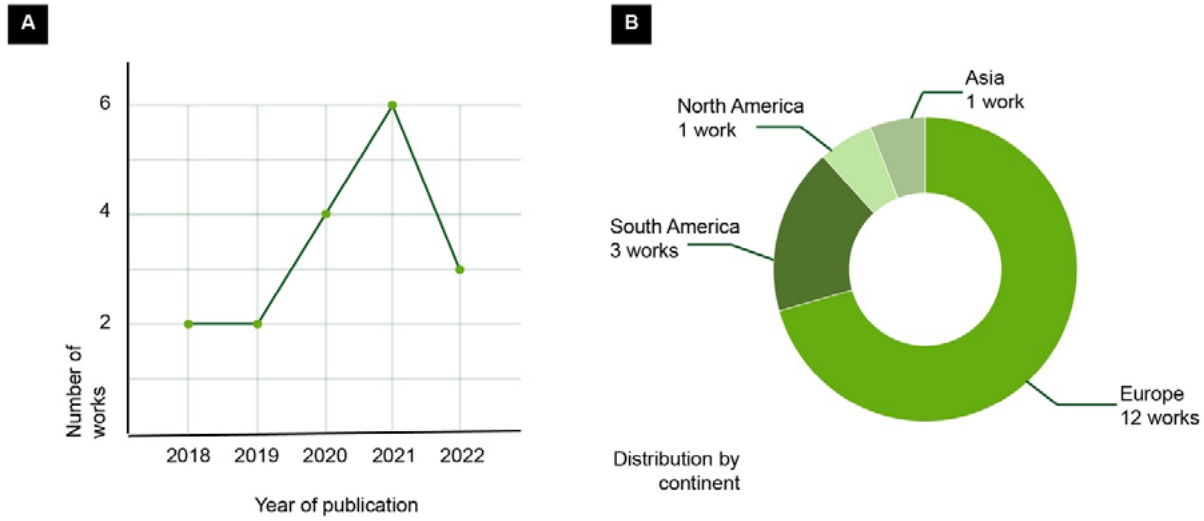

Figure 4. Literature reviewed general analysis: (a) publications per year; (b) publications by continent.

Figure 4A outlines an increasing growth in the studies on low environmental impact within design companies, with most publications from 2020 and 2021. Furthermore, while the discourse aimed to be analysed globally, Figure 4B demonstrates a concentration of research in the European continent.
The analysis revealed frequent interchangeable use of terms such as 'approaches,' 'strategies,' 'methods,' and 'tools,' potentially leading to ambiguity. To clarify, we adopted the following definitions:

- Approach: A perspective-driven way to address a problem. The most general of these terms;
- Strategy: A structured plan to achieve specific goals;
- Method: A systematic procedure applied to a task;
- Tool: An instrument that facilitates the application of methods or techniques.

From the seventeen identified documents, ten were primarily focused on strategies, three concentrated on methods, two examined specific tools, and two offered a broad overview of the evolution of approaches relating to design application in firms. In the next section, we present the SSLR results divided into the abovementioned terms and under the sustainability and circularity lenses.

4.2 Literature Review

Sustainability Lens

As outlined in the introduction, the concept of environmental sustainability has been recognised in the product design industry for a considerable time, manifested through different labels. Two perspectives representing low-impact design in the literature review are DfS and Design for the Environment. DfS (focusing on environmental requirements) involves a more comprehensive approach, considering social, economic, and environmental goals in product design, demanding broader changes in business and society. DfE focuses on reducing environmental impacts through specific technical improvements (Delaney et al., 2022).

Delaney et al. (2022) and Bumgardner and Nicholls (2020) have extensively contributed overviews on this topic, identifying numerous approaches for embedding these perspectives into the product design process. The former provides a holistic view of recurrent factors when designing for environmental sustainability. They emphasise the integration of DfS in products and the use of tools like LCA, checklists, and software, underlying the challenges in integrating them, such as the significant time and quantitative data required and the need for specialised expertise. In this regard, they present a new design process for and from product designers, integrating stages on how and when to consider the identified environmental sustainability factors. The latter, instead, present DfS practices in wood furniture, remarking on the complexities these principles impose, for instance, adding steps and costs to the design process. They investigate approaches like green manufacturing, green supply chains, ecodesign, sustainable materials, biomimicry, and eco-labelling, highlighting their influence on firm competitiveness.

Three articles propose strategies as innovative DfS frameworks. Baldassarre et al. (2020) discuss the need to integrate DfS theory into business, noting the challenges of abstract philosophies in ecodesign, product service systems, business models, and collaborative ecosystems. The problems they highlight are linked to specific, actionable guidance, the enormous change needed in the operating company system, the financial costs, the lack of stakeholders' commitment to sustainable goals, and the rebound effects of poorly studied strategies. Furthermore, the limits in communication and language between the academy and industry are evidenced. In this regard, they integrate existing DfS theory into a new framework within business concepts and give some recommendations to deal with these issues. Ruy et al. (2019) describe a framework for implementing DfE in the conceptual design phase, highlighting the need for environmental assessment approaches applicable across product concepts. His framework is based on an analytical hierarchy process for conducting product concept evaluation, determining which approaches will help achieve environmental performance. This framework is mainly based on strategies related to the physical dimension of the product, represented by the use and consumption of material resources. Lastly, Benabdellah et al. (2021) acknowledge the lack of specific classification to consider suitable methods for DfS. To overcome these challenges, they suggest a strategic framework to integrate Design for X with knowledge management (KM) techniques. The authors propose using KM and an ontology-based approach (Ali et al., 2020) for a more structured environmental consideration when designing.

Rossi et al. (2019) and Rossi et al. (2022) present new methods to improve the practical application of ecodesign in industry. In the first article, it is noted that prioritising legal, performance, cost and aesthetic factors over environmental considerations creates a barrier to integrating sustainability into business and design practices. The authors suggest the "Product Impact Index" method for aligning these priorities with environmental objectives, improving the evaluation and comparison of possible solutions. On the other hand, the second article discusses the need to support companies in integrating their productive data related to environmental, functional, and economic aspects into the design process. They propose using this information and making more environmentally aware decisions.

Finally, Ahmad et al. (2018) analyse existing tools for DfS, noting their failure to integrate environmental, social, and economic sustainability, evidencing the need for approaches encompassing a broader sustainability scope in the design processes. They classify tools published from 2007 to 2017, highlighting an inconsistency in using those tools and suggesting a gap in similar, more recent research.

Circularity Lens

The analysis shows that CE and CD, aiming for zero-waste products, are still in the early adoption stages in product design companies. Furthermore, the review suggests a broader consideration of strategies to reach CE through CD and less focus on tools or methods. Indeed, Sousa-Zomer et al. (2018) note that the ground of CE and CD is still unexplored in business. They claim that using cleaner production (CP), a known principle, can help the CE, especially in product design (even if it is not a strictly design-related area). They found CP practices key for CE at both product optimisation and micro-level production stages, linking to broader CE aspects like waste management and other organisational processes.

Lindkvist Haziri and Sundin (2020) and Boorsma et al. (2021) both advocate for the design of a remanufacturing (DfRem) strategy to improve environmental sustainability within CD. The former proposes a framework addressing DfRem challenges, particularly the feedback loop from remanufacturing to design, aiming to systematise this feedback into the product design phase for better DfRem application. The latter stresses the need for early integration of remanufacturing principles in design, citing challenges like technical integration and scalability. They note a disparity between the theory and practice of DfRem, suggesting that design management is crucial for bridging this gap. Both studies initially validate their proposed frameworks but emphasise the lack of additional testing and refinement.

Bressanelli et al. (2020) review CD strategies in the appliance sector, noting their ineffective integration in the design process. They stressed the incremental adoption of strategies like the 4R hierarchy, servitisation, and digital tech use. However, they identify challenges such as reduced efficiency from incomplete 4Rs implementation, issues like the complexity of service-based models, operational challenges, scalability difficulties, and investment risks in new technologies. On the other hand, Valusyte (2021) presents an overview of the implementation of CD strategies in manufacturing, noting their growing recognition but limited real-world use, especially in SMEs. The author points to a reactive rather than preventative approach to value chain impacts. Key challenges include terminological confusion across different fields and insufficient information on the practical application of CD.

De Kwant et al. (2021) and Hansen and Schmitt (2021) introduce strategies to facilitate CD implementation, addressing its underexplored role in business models and product innovation. De Kwant et al. focus on a framework to identify cost, cultural, and policy barriers and integrate DfS theory with circular business principles. On the other hand, Hansen and Schmitt identify barriers like designer mindsets and supply network issues, proposing "innovation communities" for more humanistic and collaborative solutions to circular product innovation challenges. They suggest collaboration and networking with diverse stakeholders are necessary for succeeding in sustainability-oriented innovation.

Introducing methods, we found Boorsma et al. (2022) that decided to evaluate circularity at the product level, reflecting on the designers' readiness level for implementing CD. They state that transitioning from linear to CD demands a new designer mindset for developing multi-use cycle products. They propose the "Circular Product Readiness" method to compare CD scenarios and apprise designers' capabilities in CD, identifying strengths and areas for improvement.

Lastly, regarding CD tools, Hildenbrand et al. (2021) point out that most existing products are not designed and manufactured with circularity concepts that consider consumer use, nor the existing tools for design. Thus, they examine the implementation of two tools within real-world case studies to understand strategies within CD that consider users and the end of use. They emphasised user interaction and feedback as fundamental to achieving circularity.

4.3 Interview Findings

The interview results consolidated empirical information gathered from six testimonials from Italian practitioners within Italian design firms (two for the same company). We explore their approaches for design with low environmental impact and the challenges of incorporating these principles into their business.

Table 3. Summarised information about the companies (and participants) in the survey.

Company size (workforce)	Design Category	Recognised sustainability and circularity efforts	Role of the interviewer
10,001+ employees	Power suppliers – Technical products – Products for electrification	Application of Life Cycle Thinking (LCT). Transparency and communication.	Global Sustainability Specialist. Senior Designer Engineer in R&D.
201- 500 employees	Design furniture for home and working environments	Sustainability strategies in its production and design process. Certifications and transparency. LCA and redesign.	Sustainability Design Manager.
51-200 employees	Home furniture with meaning – Interior home decor	Application of sustainability as a business philosophy. Incorporation of ESG and SDGs targets.	Product Marketing and R&D projects.
201-500 employees	Notebooks, bags, and accessories	Durable products. Certified materials. Use of recycling or reprocessing strategies. Social programmes.	Global Marketing Manager and ESG team member.
501-1,000 employees	Light Design, Outdoor lighting, and Architectural Lighting	Certifications and transparency. LCA and redesign. SDGs targets. Materials, energies, and health.	Head of Innovation Design and Sustainability team member.

The interviews illustrated the feasibility of addressing sustainability through design and the possibility of rolling-out DfS and CD approaches. However, they underlined the complexities and the need for a deep organisational commitment and a change of mindset not only of individual practitioners but of the whole organisation. The interviewers highlighted that one of the current strategies is the creation of sustainability teams (most of them have achieved this in the last four years or less), recognising the complexity of sustainable decision-making and execution. These teams often include people with extensive knowledge of the company and young professionals from diverse areas. Today, they are proving to be strategic in integrating DfS into the corporate culture and addressing the progressive evolution of practices. Multidisciplinary collaboration was recognised for fostering robust dialogue on sustainable challenges and innovations.

A demand for new professionals with a holistic understanding necessary for pragmatic implementations was revealed. There is a growing inclination towards internalising designers with technical skills, like LCA proficiency, to enhance in-house capabilities and create bespoke sustainability models. Indeed, despite the struggle to find such candidates, four of six participants recognised the implementation of this knowledge internally and the development of tools for their design development process. Participants underscored

that firms are developing customised toolkits, guidelines, and checklists and using LCA to measure the impact with external consultancy support. LCA emerged repeatedly, evidencing an essential first step for guiding design, processes, impacts, and ensuring the consistency of successful strategies across various product lines.

LCA was also related to compliance and the standards or certificates companies aim to achieve. For example, participants emphasised following ISO 14040:2006 for Life Cycle Assessment and ISO 14006:2020 for environmental management systems and incorporating ecodesign (ISO, 2006, 2011).

Participants point out annual training courses as necessary, emphasising effective communication on sustainability topics across different practice areas. Furthermore, most of them expressed that agenda creation for sustainability and KPIs related to product development issues were considered necessary. Indeed, the interviewers say there is a need for strong partnerships with other companies and alignments with suppliers, sharing their sustainability objectives.

Unique insights include forming "good practice books" and "material libraries" and suggesting tools for archiving and learning from past successes and collaborations. Participants define this approach as instrumental in fostering continuity and progress in DfS practices.

Materials design and innovation, particularly the exploration of emerging, bio-based and recyclable options, surfaced as a strategic priority for sustainable and circular design strategies. Yet, reconciling environmental benefits with aesthetic and durability standards presents a significant ongoing challenge and an area ripe for further research that, as interviewers claimed, is already on their agendas. Indeed, in some cases, creating product-service system options is necessary to keep materials in the loop.

Despite progress, ongoing and evolving challenges report the need to continually develop skills, tools, and collaborative efforts to integrate sustainability fully into product design and business strategy.
The resulting practices adopted by companies to advance the design of low environmental impact are the following:

- Formation of multidisciplinary and transversal teams equipped with specialised skills;
- Onboarding of professionals with related expertise and internalisation of such competencies;
- Measure impacts as a starting point for undertaking sustainable initiatives;
- Creation of tailored tools and methodologies;
- Create/propose services that complement sustainable product offerings;
- Continuous internal training and knowledge updates;
- Clarifying internal terminology related to sustainability;
- Engaging partners and suppliers in shared sustainability objectives and KPIs;
- Creation of a sustainability agenda;
- Compiling best practices;
- Adhering to legislative requirements and pursuing relevant certifications and standards.

4.4 Integration of Findings, Reflection, and Future Directions

We discovered convergence in implementation and challenges but also recognised a gap still evident within theory and practice.

The literature review reveals a critical paradox: the abundance of conceptual frameworks, strategies and tools focusing on environmental requirements in product design contrasts with few long-term reports on their application in companies. On the other hand, the growing literature on CE shows a limited and superficial focus on the physical part of the product design, even though it is essential in this new economic model (Heras-Saizarbitoria et al., 2023).

Within the literature, we found that despite admirable but isolated efforts, DfS and CD often fail to create meaningful impacts that can effectively integrate product design with strategic business objectives. The theoretical exploration of DfS and CD is well documented, but practical applications in business are sporadically reported, leading to a fragmented understanding of its application. While case studies may shed light on specific instances of practice, they provide only snapshots, leaving a notable gap in longitudinal research (or long-term approaches) that could reveal how organisational practices and strategies evolve over time. We recommend that future literature integrate sustainable product design principles within company culture objectives and practical operations.

With the review, we identified multiple (less or more complex) tools and methods, such as LCA, sustainability checklists, and software packages, to aid low-impact design. Nonetheless, these tools encounter significant barriers, including complex data requirements and the need for designer expertise, pointing to a misalignment between tool availability, their practical use in design processes, and the practitioners' skills. More simplified methods and tools are often criticised for not being sufficiently accurate. The specific ones, instead, receive criticism for not being scalable. Additionally, a prevalent issue of terminological confusion on definitions among sustainability and circularity concepts and the usefulness of methods and frameworks often limits effective communication among academics, educators, and practitioners. These findings are consistent with interview testimonials. Participants encountered challenges performing LCA or using ecodesign softwares without consultant support or dedicated professionals. They also expressed that academic or generic tools and methods are not always efficient, but creating their own following the firm requirements and values demonstrates more effectiveness. It is therefore suggested that developing flexible, updatable ad hoc models inside firms could be a good direction for future development.

Furthermore, interviewers also indicate confusion in vocabulary. However, they were mostly aligned with terms of Ecodesign directives (EC, 2009). This repeated claim suggests that even with the present efforts for alignment in communication, more rigour is necessary. A good initiative could be to vigorously implement the terms indicated by the "International Organization for Standardization" (ISO, 2006).

The literature review and interviews continuously stressed that stakeholder involvement is crucial for successfully adopting DfS and CD and establishing R&D partnerships with shared KPIs. Furthermore, collaborative environments, multidisciplinary teams, and visionary management were repeatedly found essential for achieving environmental requirements in product outcomes. It would be interesting to analyse and share more information about these teams' formation and work to propose companies' new models. However, they are still emerging, and it is unclear where and how they will operate.

An expected result was confirmed with the literature review, i.e., the importance of incorporating sustainability and circularity principles from the initial stages of the design process. The authors highlighted that this incorporation requires equipping designers with skills and knowledge to navigate DfS solutions effectively within the business implications. In contrast, interview participants emphasise this need differently. They explained that the challenge is integrating sustainable and circular principles into the company's culture and making them imperative in the design process, production, and marketing. Both approaches seem to be valid and compatible. Additionally, some practitioners underscored materials design and innovation as fundamental, advocating that materials are central in all DfS and CD strategies, and there is a growing need for more standardisation and recognition around emerging materials and their potential applications (Duarte Poblete et al., 2024). Future research should analyse them in depth to bring more specific data and results.

Recent literature highlights that barriers such as consumer disinterest and weak regulatory frameworks are progressively being overcome thanks to growing consumer awareness and improved environmental regulation. Indeed, the older literature was characterised by these limits. At the same time, the interviewers revealed that today's consumers, customers, and new legislation are putting pressure on companies to propose design solutions to existing problems and anticipate and prevent new challenges. In this regard, three participants acknowledge that the best way to face this challenge is to see it as a competitive

advantage, where investments will pay off through future innovation. We argue that, despite the difficulties in complying with regulations and standards, they are valuable strategies for achieving concrete goals in environmental sustainability.

While the literature on these fields is broad, empirical research is still needed, emphasising longitudinal studies and deeper engagement with practitioners. This approach could overcome the gap between theory and practice, fostering a more synergistic and impactful collaboration among academia and industry. Sustainability concerns in design business practice are not new (Gaziulusoy, 2015). However, the continuous emphasis on addressing them in recent literature highlights the urgency for industry and academia to join forces. Furthermore, the slow pace of change in business sustainability underscores a need for accelerated action, not just in product design.

By analysing the literature results and the interviews' findings, we address the research questions, i.e., the current situation of product design companies in implementing environmental sustainability practices and the constraints they face in the business world. By examining the data, we have identified key trends, challenges, and strategies for pursuing low-environmental impact design within the industry.

Table 4. Summary of implemented aspects and challenges in product design companies.

Implemented aspects	Common challenges and limitations
Traditional DfS and CD approaches (guidelines, tools, and methods).	Too general. Lack of scalability. Insufficient integration within company culture and operations factors. Complexity of use or understanding of the results. Extensive data requirements. Time consuming. Lack of commitment from users. Complex vocabulary. Expertise required.
Tailored guidelines, tools, and methods.	Time consuming. Large investments. Expertise required.
Principles (e.g., recycle, reuse, reduce, etc.) and strategies (DFX, design for disassembly, design for circularity, etc.)	Incorporation from the initial design stages. Consistency in all projects. Coherence with company culture.
Materials Design & innovation	Harmonise environmental benefits with aesthetic and durability standards. Lack of specific professional profiles. Progressive updates and uncertainty in time.
Directives and standardisation guidelines.	Time consuming. Complex terminology. Lack of knowledge about its success. Continuous updates and insecurity.
Training and awareness regarding sustainability and circularity.	Isolated implementation (just one area of the company). Terminology confusion and ineffective communication across sectors. Time consuming. Lack of a visionary perspective.
New entries, multidisciplinary teams, and collaborative environments.	Lack of specific profiles. Deficit in transdisciplinary skills. Time and resources.
Strategic Partnership	Lack of responsible partnering. Stakeholders' commitment to sustainable practices. Lack of shared objectives and KPIs.
Visionary ESG management	Difficulties in finding experts with holistic/transversal and visionary management vision. Large investments.

5. Conclusions

The literature and testimonials on environmental sustainability approaches and their rolling-out in product design firms were systematically collected and analysed as part of this study. The main aim was to assess the current situation of product design companies in adopting low environmental impact design practices and to understand the practical limitations of the theoretical approaches within the related strategies, methods, and tools. Seventeen works between 2018 and 2023 were analysed following a semi-systematic review process that depicted the literature's contemporary frameworks of DfS and CD. In-depth interviews with practitioners from five Italian companies provided further real-world context. As a result of the study, current practices of DfS and CD adopted by companies to advance low environmental impact design were identified and reported. It also offered insights and possible future directions for companies and academics to enhance DfS and CD and bridge the gap between theory and practice.

Reflecting on our work, future research may address this study's limitations. The literature review was limited by a keyword-based search within scientific databases, potentially excluding emerging studies. Additional methodologies, such as snowballing, could broaden the research scope in future work.

Moreover, the qualitative data collection through the interviews was confined to the Italian industrial sector. Thus, further research in other companies, countries, and continents should be conducted in future studies. The data collected from the interviews does not encompass the entire industrial sector but provides a snapshot of various aspects from different design categories. Additional interviews and observational studies across a broader range of companies are recommended to deepen the understanding of the industry's current state.
Lastly, while structured, the study's qualitative approach to data interpretation is subject to the possibility of alternate analytical perspectives. However, the insights derived from this process contribute meaningfully to the ongoing discourse on implementing sustainability and circularity in design for business practices.

About the Authors:

Sofia Soledad Duarte Poblete, Ph.D. candidate at the Politecnico di Milano. Her research focuses on materials designers for environmental sustainability in design firms. She explores emerging materials in product design, and materials-driven design practices for companies to foster the transition towards sustainability.

Laura Anselmi, architect, Ph.D., and Associate Professor at Politecnico di Milano, Design Department. She is the Scientific Supervisor of the Product Usability Lab and collaborates with IDEActivity Centre, and the Materials Design for Transition research group. Expert in product design.

Carlo Proserpio, since 2003 he has been involved in business consulting and teaching support on Design for Environmental Sustainability at the Design Department of the Politecnico di Milano. He applies Life Cycle Design and Life Cycle Assessment methodologies in the development of sustainable products. sustainable products.

Valentina Rognoli, designer, Ph.D. in industrial design, and Associate Professor, Politecnico di Milano. Expert and researcher in DIY materials, design for sustainability, regeneration, biodesign, emerging materials for transition, urban and waste-derived materials, speculative materials, material-driven design, CMF, and material education in design.

Acknowledgements: The author of this paper extends heartfelt gratitude to the professionals and companies who generously dedicated their time and effort to discuss design practices for environmental sustainability within their operations. Additional thanks are extended to the reviewers, whose insightful comments significantly contributed to enhancing the quality of this paper.

KEYWORDS | URBAN INNOVATION, PROCUREMENT PROCESS, SANDBOX, NET ZERO, DESIGN FACILITATION

ABSTRACT | Transformation of the urban context is a continuous process of change, in which different interests and forms of rationality are converging. It is often the ground for agonistic forces that negotiate their values, projects and future views. (Concilio & Tosoni, 2018; Mouffe, 2000) However, in relevant innovation processes, such as urban or large scale projects, a design approach is crucial, as it helps to stay on course towards the ultimate purpose of the whole innovation process. In many urban innovation processes however, this approach is often overshadowed by considerations related to administrative or operative issues. This paper is based on the experience in an ongoing EU project, Climaborough, which is promoting a number of innovative initiatives in 12 European pilot cities in a Net Zero perspective. The first learning from this project highlights the designer's role in foregrounding the value of design in an innovative project. It does so by defining a design-based innovation process to promote initiatives for urban innovation. The paper will describe the three phases of the process: challenge definition, innovative procurement process and experimental sandbox and propose reflections on how the knowledge coming from those phases can be distilled, replicated and reused.

1. Introduction

Cities are complex systemic aggregations in a continuous process of transformation, which involves a multitude of actors, rules, infrastructure and natural or artificial agents (Colclough et al., 2019). To add complexity, multiple temporal perspectives configure evolutionary paths, which follow different temporalities: financial, strategic, ecological, social and political. The urban context is the ground on which different forces are converging and confronting. Cities are, at the same time, a problem lab, a resource pot, a market, a political arena and a place where new ideas emerge and mature (Concilio & Tosoni, 2018). In this continuous process of change, agonisms and antagonisms emerge between groups and rationalities that negotiate or fight and generate new, ever-changing forms of hegemony (Mouffe, 2013)[1].

A design approach plays a crucial role in mediating or creating the logical, material, and technical conditions for the interaction among different rationalities and different economic, social, cultural and political instances.

In relevant innovation processes, such as urban or large-scale projects, a design approach is extremely valuable to support innovation processes by framing them into the general and ultimate purpose of those processes. This is particularly evident in those cases in which urban transformation is led by the ambition of a complex systemic change, which is supposed to transition cities towards radically different scenarios (Concilio et al., 2018).

In large systems, and for the multiple actors involved in their change, design is not only an approach used to plan and direct major infrastructural changes but also a general and diffused attitude (Manzini, 2015) that must be mobilized at different levels to produce changes in small communities (niches), in urban systems (regimes) or even in the broader cultural, social, legal and economic landscapes in which cities are placed (Geels & Schot, 2007).

The challenge for design, however, is to learn how to work in such contexts and how to mobilise people, technologies and legal or organizational infrastructure to address this transition. In the last decade, several scholars have been focusing on the design perspective on this challenge (Ceschin, 2016; Gaziulusoy & Ryan, 2017; Irwin, 2015, 2018), while others have specifically focused on how niche or punctual design initiatives could be scaled up or framed in larger systemic changes (Manzini & Rizzo, 2011; Author, 2015a, Author 2015b).

2. The Net-Zero Challenge and the Climaborough Project

One of the most relevant challenges in urban sustainability transition is represented by the Net-Zero Cities (NZC) initiative. Cities are accountable for more than 70% of the global CO2 emissions (Mukim & Roberts, 2023), but they are also at the forefront of innovation, even though they are far from having consolidated methods to govern such complex innovation processes. For this reason, acknowledging the significant impact urban areas can have, the European Union identified cities as a key leverage point and the place to start a radical change in lifestyles and resource use, with the ultimate aim of reducing carbon emission by 55% by 2030 and achieving climate neutrality by 2050 (netzerocities.eu). Within the mission-oriented European program, which aims at creating interconnected actions that link climate challenges, policies,

[1] Chantal Mouffe conceptualises agonisms as a productive force that can lead to the articulation of diverse perspectives. In an agonistic democracy, the goal is not to eliminate conflict but to foster a respectful and inclusive space where competing viewpoints can engage. Antagonism instead, represents a deeper and more irreconcilable form of conflict that arises when there is a fundamental clash of interests or identities that cannot be resolved through dialogue or negotiation. Mouffe also discusses the dynamics of power and conflicts in democratic society through the concept of hegemony, a concept drawn from the work of the philosopher Antonio Gramsci. Hegemony refers to the dominance of a social group or class, based on consensus and the articulation of a dominant “common” sense. Mouffe points out that hegemony is a contested and unstable condition.

urban planning and scientific/technological change, *Climate-neutral and Smart Cities* is, in fact, one of the missions of the EU for the years 2021 – 2027. Among other initiatives, NZC has mobilized 112 European cities to accelerate the climate neutrality objective to 2030, thus becoming leaders in the effort towards the 2050 mission challenge. The 112 mission cities have been selected after a call for expression of interest launched in 2021.

The NZC initiative has mobilised a big effort in several European cities, thus helping to raise awareness of the meaning, as well as the political, social and infrastructural issues emerging from this challenge. Even those cities not funded by the NZC initiative had a chance to reflect upon policies and strategies to mitigate their CO2 emissions or adapt to the inevitable consequences of climate change.

In line with raising awareness for the Net-Zero challenge, the EU-funded Climaborough project has been designed to support NZC or cities that have applied for the NZC challenge, even when not successful. Climaborough supports 12 of those cities by employing a double cycle of public procurement for innovative project proposals that implement part of the urban climate neutrality strategy. The idea is to support projects that could generate significant changes in the pilot cities by working on different aspects, from technical feasibility to social, regulatory, cultural, or organisational issues.

In its four-year duration, the Climaborough project team will coordinate the two cycles of the procurement process by making sure that: a) the cities recognise the challenge the NZC goal represents for their specific development plans and translate this challenge into concrete actions, b) the procurement process is addressing those challenges and c) the results of the procurement process are integrated into the dynamics of change of the urban context.

The complexity of the work in these cities could be analysed in two directions:

- a vertical direction: any intervention in this project will necessarily target a niche, i.e., a very local and specific issue related to the general challenge of climate neutrality. The vertical connection between the specificity of this initiative and the more general target of (urban or regional or global) climate neutrality should, however, never be forgotten, to frame any possible intervention within scalability strategies;
- a horizontal direction: every single change in the complexity of the urban context implies the interaction of different competencies, cultures, stakeholders and technologies;

Any activity of change in this context, i.e., any design or planning activity, should take into account this complexity and raise the question of the role of a design approach in coordinating actions, navigating complexity and connecting horizontal and vertical issues.

3. An Overview of Existing Literature

This Climaborough project focuses on a specific challenge within a larger challenge referring to a wider disciplinary landscape. The larger challenge concerns urban planning and the need to integrate the inevitable instances of climate change in the design or redevelopment of urban areas. Such a challenge is characterised by a tension between mitigation and adaptation strategies (Davoudi et al., 2009). Combining the two strategies often implies an interaction between global perspectives that are implied in mitigation strategies, with specific challenges, i.e. local interventions, often related to adaptation. The challenge of climate neutrality is therefore to be framed at different scales, between the local intervention and the larger scale perspective (Shabb et al., 2023; Wu et al., 2023).

In defining the mission of Climate-Neutral and Smart Cities, the European Commission referred to an approach to multi-scalar challenges inspired by Mazzucato's mission-oriented innovation policies(Mazzucato, 2017, 2019). Mazzucato proposes such policies as a response to the most urgent global challenges. She does so by articulating the missions in a framework that mobilises different economic and

technical sectors through the promotion of mission projects (Miedzinski et al., 2019). This approach creates a framework for policymakers to address investments into meaningful innovations, creating a clear alignment between the scale of each proposed solution - the lower scale challenge -with the larger goal of climate neutrality.

The transition towards climate neutrality can be described through Geels multilevel perspective (Geels, 2010). Geels describes large transitions, such as the transition to climate neutrality, as a dynamic process that connects: (1) innovation in niches, e.g. small, protected environments in which innovation may happen and develop; (2) change in institutional regimes, i.e. the set of rules, norms and practice that shape the current system and (3) transitions to new socio-technical landscapes, which represent the broad socio-technical, economic, and cultural context in which niches and regimes operate. Design and urban planning operate at different scales in this process: while design has often been focused on interaction at the niche level, e.g. among individuals, or communities, the planning scale often refers to the regime level, as it concerns the entire set of tools, measures, and actions that cities may provide to the climate neutrality mission. (Arcidiacono et al., 2023). The role of design in innovation processes in cities has been explored in the work of policy and innovation labs (Thorpe et al., 2016; Thorpe et al., 2018; Voytenko et al., 2016) and in different projects, some of which have directly influenced the definition of Climaborough paradigmatic view and methodological approach. Among them is, for instance, the Designscapes project, which studied the role of design in the innovation processes between niches and landscape transitions (Concilio, De Götzen, et al., 2018); and the T-factor project, which suggested participatory design approaches to mission-oriented urban regeneration processes (Marmo et al., 2023). The methodological approach in the Climaborough project is the result of a combination of the theoretical frameworks derived from those projects and the operative experience of innovation assessment in cities (Colclough et al., 2019).

4. Methodological Approach

The working cycle adopted in Climaborough is based on a continuous conversation between the cities and the Climaborough design team. An overview of the process could be articulated in three phases:

1. **Challenge definition**: an initial phase in which each city's challenge is collaboratively crystallized and defined, main stakeholder groups that are affected by, or affect the challenge, are identified, and a number of use cases that elicit the details of the challenge and the institutional, infrastructural, social and data-related are developed. This phase serves as a foundational preparation for the public procurement process.
2. **Innovative public procurement**: the Climaborough project uses a preliminary market consultation, based on a preliminary negotiation dialogue with potential solution providers.
3. **Exploratory Sandbox**: this phase consists of preparing an experimental playground for awarded solution providers and municipalities to experiment with ways to apply the proposed solution to the urban context of the pilot city. A sandbox is a tool legally recognized by the EU (European Commission, 2023). The experimentation conducted within a sandbox can extend into regulatory, technical or societal realms.

It is worth noticing that the team involved in those phases had different competencies that have been used according to the phases of the project. In the challenge definition phase, the conversation with the pilot cities has been mediated by an innovation expert and by the '*city angels*' (i.e. two partner organisations: an association of municipalities and a lab working on urban transformation projects and have long-term experience in working with public administration) and designers, who collaborated to the definition of facilitation tools. The procurement process has mainly been coordinated by partners with long administrative experience. The nature of the experimental sandbox is still to be fully explored and will possibly involve designers, the above-mentioned innovation experts and the city angels.

At the time of the redaction of this paper, the cycle is not yet closed, therefore, this paper will explain the work in the three phases and propose some reflections about the learning in the first two phases and the forecast on the work to come.

4.2 Challenge Definition

In the first phase, the Climaborough consortium worked on the definition of a framework for the whole innovation cycle. This phase started about four months before the launch of the tender and continued during the tender. The purpose of this phase is to frame the whole innovation process, in preparation for the public procurement. In this phase, the pilot cities are engaged in a series of meetings, in which they are asked to identify:

- **A challenge**, concerning the main net zero objective for the city;
- **The innovation potential**, e.g. the ecosystem that can support (or hinder) the innovation process, the assessment of such potential was based on four pillars: Framework conditions, network enablement, innovation in action and sustaining value. The conversation with the pilot cities consisted of exploring the components of those pillars (the hexagons in Figure 1);
- **The actors in the ecosystem**, i.e., the users of the solution, but also the relevant stakeholders, such as business or public sector, the ecosystem has been mapped taking into account the level of interest and opinion of the stakeholders (figure 2);
- **Relevant datasets,** that are needed to build and evaluate the solution and will be integrated in a project platform;
- **Use cases**, which define possible scenarios for addressing the defined challenge and that elicit requirements, specifications and details that can be used especially in the description of the challenge as well as for helping the city representatives adopt a citizen-centred point of view (figure 3).

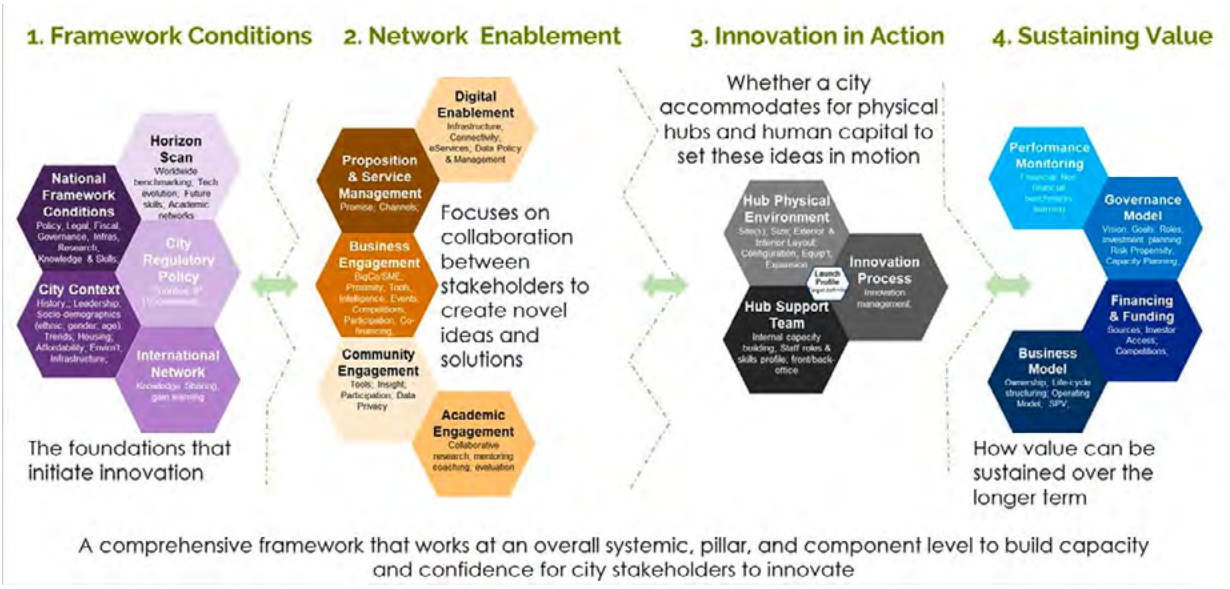

Figure 1. The 4-pillar systemic urban innovation framework. Source: (Colclough, 2023).

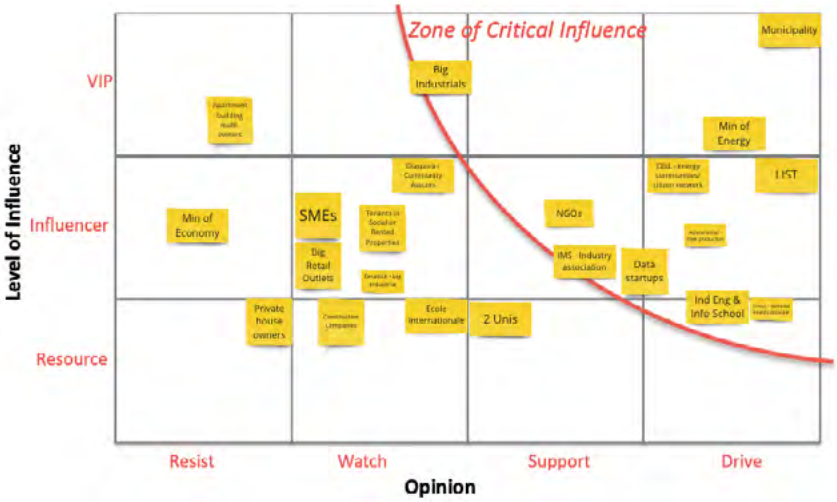

Figure 2. Map of the ecosystem actors by level of influence and opinion.

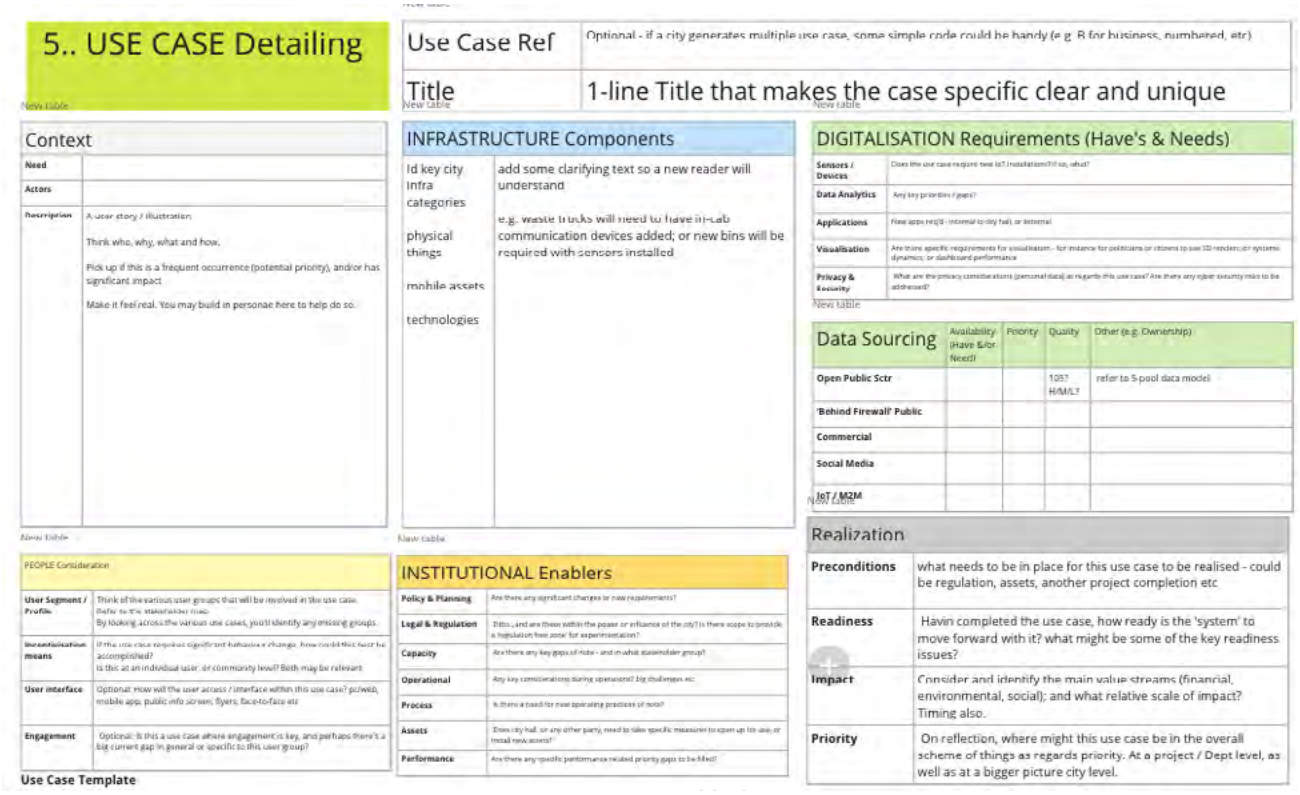

Figure 3. Use case template.

The project defined two *Climhubs*, i.e., two thematic areas: one hub focuses on urban challenges related to energy and mobility, while the second focuses on waste and circularity. Each pilot city's challenge can be associated with one of the hubs. The hubs are meant to support knowledge generation and exchange between cities addressing thematically similar challenges.

The pilot cities are either working through individual interactions with the design/research team or by exchanging knowledge with other cities in the same hub. Each meeting, whether individual or within the hub, has been facilitated by design-driven frameworks that supported the discussion on each of the themes identified above.

4.3 Innovative Public Procurement

Unlike the normal tender processes, the Climaborough project used an EU legally recognized tool, the preliminary market consultation, which makes it possible for municipalities (launching the tender) to open a dialogue with possible participants to the tender before they send the final offer (Sorokina, 2022). The preliminary market consultation consisted of a general information meeting with the potential applicant in each city. The knowledge acquired in the challenge definition phase is used in this phase to provide the applicants with all the necessary information to participate in the tender. This knowledge, together with the requirements elicited in the challenge definition phase, is distilled in the tender call and specified in one of the appendices of the call.

The public procurement process is divided into two phases: in the first phase, proposals are presented without specification of the budget, to be discussed in a one-to-one negotiation between the city and the proponent. It is crucial, at this point, that the city has a clear picture of the most relevant implications of the solution on the city ecosystem. In this phase, cities can propose changes that the proponent can include in a second submission (the second phase), which will also include budget details.

4.4 Exploratory Sandbox

This phase consists of preparing an experimental playground for innovators and municipalities to experiment with how to include new initiatives in the urban environment. In experimental contexts, a "sandbox" typically refers to a controlled environment where researchers can test hypotheses, explore ideas, and conduct simulations without risking any significant consequences that could instead occur on a real-world or a city-wide scale. This concept is often used in fields like computer science, where sandbox environments provide a safe space for testing software or algorithms without affecting the broader system, or in game development, where designers use sandboxes to test game mechanics, level designs, and player interactions before integrating them into the final product. Generally, the concept of a sandbox in experiments allows researchers to iterate, refine, and validate their ideas in a controlled setting before applying them in real-world scenarios. It provides a valuable tool for experimentation and innovation across various disciplines.

The European Commission provided some guidelines for the definition of the concept of sandbox (European Commission, 2023); The experimentation conducted in a sandbox can span regulatory, technical or societal realms. Regulatory experimentation may involve a temporary loosening of existing legal and regulatory frameworks to enable the testing of innovative technologies, products, services or approaches, which are not fully compliant with these frameworks. While the term sandbox has often been referred to the regulatory aspects of the experiment (Nesta, 2019), the European Commission also considers other experimentation tools to foster learning and experiments: testbeds and living labs. The former mostly focuses on technical aspects, whereas the latter refers to the social aspects.

All the aspects, regulatory, technical and social, should be tested through prototypes, or demos: the conversation with the cities is aiming at highlighting the most relevant technical, social and regulatory aspects that are expected to be tested and evaluated. Figure 4 is a snapshot from the conversation with one of the pilot cities, using a Miro board.

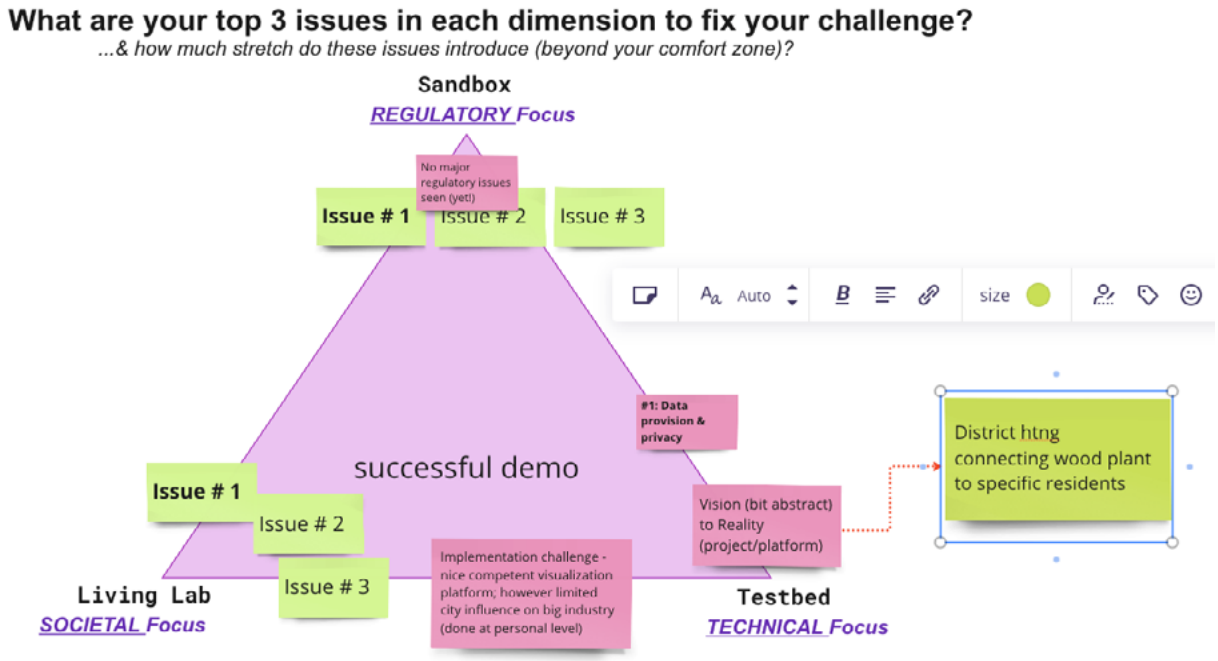

Figure 4. Graphic representation of the characteristics of the experimental sandbox in one of the cities.

The three aspects of the experimental sandbox refer to different disciplinary areas: for years, living labs have used specific methods and tools, such as design jams, design sprints, workshops and systemic prototypes to engage communities in co-creation activities (Leminen et al., 2017; Schuurman et al., 2012). Technical aspects have also been used with different forms of modelling or prototyping. Regulatory sandboxes are used in healthcare, energy, transport, fintech and data (Nesta, ND), but they represent a relatively unexplored domain explored in the design discipline. Relevant explorations in this area have been undertaken by Nesta (Nesta, 2011, 2019, ND)and IDEO (I. Nesta, 2016), and suggest the use of different prototyping strategies to address different levels of complexity, from individual interactions to large regulatory systems.

5. Discussion

At the time of writing this paper, the project is far from being completed. The preparation phase has led to the preliminary market consultation and the preparation of the call for tender. A good number of solutions have been proposed and will be evaluated according to the appropriate procedure, as required by EU regulations.

As previously mentioned, this paper is the first opportunity to get an overview of an ongoing design research project, looking at what worked or not and the challenges to come. This is an *insider* overview, as the authors of this paper are directly involved in the design of the various phases, in the interaction with the city and in the negotiation of the process with all the partners in the project's consortium. This implies that, rather than a completed experience, the authors intend to propose a discussion about the perspectives and the learning from this first phase of the project.

5.1 Different Perspectives

The Climaborough project includes twelve cities, eight of which are *leader* cities (i.e. those that participate in the first cycle of the procurement processes), whereas four other cities are participating as *followers* (meaning that they will be involved in the second call for tender). Furthermore, leader cities in one hub will become followers in the other hub, which means they may be able to promote some activities in areas that have not been included in the first procurement process. Some of the cities are relatively large (Torino, Grenoble, Sofia, Athens), whereas others are much smaller. The administration structure is, therefore, quite

different, as different are the roles of the personnel participating in the project, from public servants working in offices dealing with specific problematic areas (e.g. urban waste, mobility, energy), to external consultants working with the municipalities. Finally, the different sizes of the pilot cities imply a different decisional structure: the big cities are obviously bounded by a more structured decisional process, whereas the smaller have a thinner, possibly more agile organization, but some of their decisional processes must be coordinated at the regional level. The diversity of perspective implies the need to find different *languages* to talk to cities and a unified strategy to organise the dialogue in those languages. The graphic format and the templates have been valuable boundary objects to support the conversation.
The different perspectives also impact on the capability to react on the pilot cities side, which means that the capability to influence decisions at the municipal level is different. This will possibly affect the way the sandbox can be organised. A regulatory sandbox, in which certain regulations are suspended to support experiments, may not be possible when the point of contact between the project and the city is not embedded in the municipal administration. On the contrary, personnel who work on specific municipal missions, such as waste reduction or digitalisation of public transport, may be more *embedded* in the administrative logic, thus they may find it hard to accept a different perspective, such as a broader view towards a circular economy, of models of mobility that support the reduction of circulating cars. The challenge in designing the sandbox will therefore consist of balancing the perspective on the specific problem and the connection with the overall themes of the Net Zero Strategy.

5.2 The Complexity of the Topics

To be compatible with the NZC goal, the change the Climaborough project is expecting to bring about in the pilot cities must be systemic, meaning that it needs to involve several aspects of the technical, social and organisational infrastructure of the city. On the other hand, the point of contact from the city is a person, or a small group, with specific competencies. What the project asks them is to enlarge their perspective beyond their competencies: experts on waste, for instance, are asked to provide information about available urban datasets or to invite other municipal public servants to the conversation. In this case, the role of design has been to provide tools for identifying relevant information about data, infrastructure, stakeholders, and institutional enablers, as for the use case templates in Figure 3.

5.3 The Drop and the Ocean

Experimenting in cities is not a new practice in urban projects, especially in EU-funded projects. Other projects tried to engage some pilot cities in the introduction of innovation and in following up on the transformation that this could cause. The level of engagement of cities, however, did not always live up to expectations, especially when the experimental phase required a complex and systemic effort. The advantage of having a procurement process as part of the Climaborough project has been to keep the interest of public servants and participants alive because the process implies very specific legal responsibilities and obligations for the cities.

On the other hand, the tangibility of the objective (the solution coming from the tender) risks narrowing the attention of the pilot cities partners on the technical, organisational or legal practicality of the solution, rather than extending the perspective to the systemic goal of climate neutrality.

The project team used the metaphor of the drop (the specific solution coming out from the procurement process) and the ocean (the systemic goal of climate neutrality at the urban level). The dialogue with the partners in the pilot cities always started from the representation of the interaction between the specific intervention, for which the procurement process was mobilised, and the climate neutrality framework and roadmap, trying to frame all the phases (challenges definition, identification of users, identification of datasets and the application of solutions) into the broader Net-Zero Goal, that should validate the pilot city strategy (Figure 5). It is clear that the single solution is not going to have any significant quantitative impact on the positioning of the city with respect to the climate neutrality goal, however, it is important to validate the solution with respect to the infrastructural changes they may require and the opportunities to amplify

the impact of the single initiative. This also implies eliciting considerations about the horizontal scalability of the solution (i.e. its reproducibility) and its vertical scalability (i.e. the possibility of integrating each solution in the institutional framework of a NZC strategy)(Moore et al., 2015).

This challenge is also very relevant in designing the sandbox. At this stage, a sandbox is a unique opportunity for designers to support experiments and test visions that can go beyond the existing regulatory, technical or societal limitations. However, the challenge for the design team is to keep the vision alive during and after the experiment, test and validation phases, possibly proposing forms of systemic prototyping or exploring scalability strategies to amplify the outcome of the experiment.

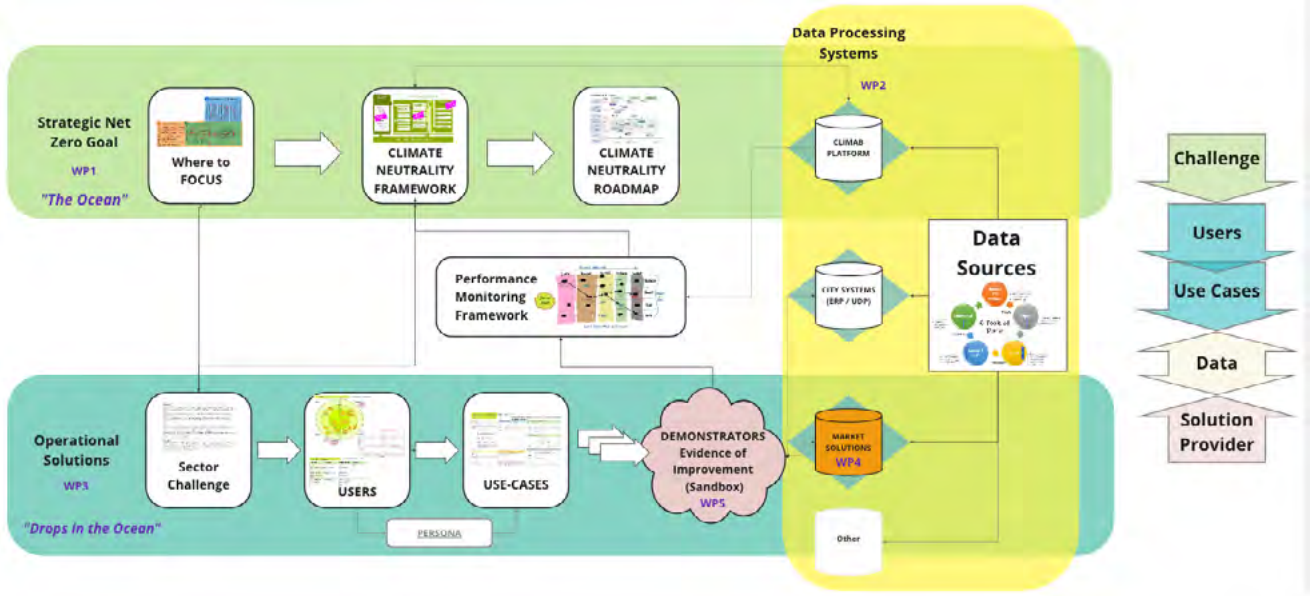

Figure 5. Linking the phases and investigations in the project with the systemic Net Zero Strategy.

5.4 The Hubs

As mentioned above, the twelve cities involved in this project are divided into two *Clim*hubs, focusing on 1) energy and mobility and 2) waste and circularity. So far, the work in the hubs consisted in sharing experiences and information in co-creation workshops. Hubs have worked as thematic areas, but also to facilitate the workshop organisation. However, the hubs are meant to have a broader scope in the project, namely to become an opportunity to develop and exchange specific knowledge, coming from the learning and the experiments in the sandbox. An activity of co-creation among the sandbox could also be proposed, that could amplify the result of each single sandbox or could test solutions across the pilots.

The hubs could become the legacy of the Climaborough project, after the funding period, possibly including new cities and becoming a repository of knowledge for cities that aim at implementing climate-neutral strategies. However, this poses some questions about the legacy of this design research project: the knowledge exchange in the Climhub is strongly supported by the project team, in particular by the city angels and the mediation of the design and innovation experts. The question emerging from the scenarios of a design research project like Climaborough is: to what extent is this knowledge reusable without the mediation of the experts and the design team? Can one assume that the collaboration between the team and the pilot cities develops a sort of *diffuse design capability* in the public administrations involved in the project? Can one assume that the knowledge repository represented by the Climhubs is effectively used also by cities that have not participated in the project? To what extent is the mediation of design and innovation experts essential to support climate neutrality innovation in cities? Finally, can the interaction for the design process be codified (for instance through a roadmap that indicates the necessary steps in the process and the tools used in each step) to distill the knowledge from the perspective of its replicability?

Those questions suggest an investigation of the model of support to design and innovation to large public systems, like cities, a question that has already been discussed in relation to the role of policy and design innovation labs around the world (Bailey et al., 2016; EUPAN, 2018; Holierhoek et al., 2019; Kimbell, 2015; Siodmok, 2017), but also in relation to the role of living labs (Nesti, 2018; Steen et al., 2017).

6. Conclusions

This paper is approaching a design problem, that concerns two levels of complexity: the complexity deriving by the convergence of multiple social, technological, organisational and political issues in the urban context and the complexity related to the multi-scalar dimension of the problem of climate neutrality.

The first dimension implies the role of design in the development of innovation at the systemic level, making sure that innovation processes are properly metabolised by the urban ecosystems and integrated into a sustainable transition process. In this sense, the paper reveals the valuable role of design in preparing the ground for procurement processes and in envisioning possible experimental conditions for innovation to be prototyped, tested and developed.

The second dimension concerns the scalability of the process, which means its replicability within the same urban context or in other urban contexts and the creation of a social, technical and institutional context that would support the replication and the diffusion of innovation. In this sense, design knowledge is valuable in defining collaboration tools, that help the actors involved in the process to scan the innovation capacity of the ecosystem, and to figure out relevant innovation conditions and the institutional enablers (e.g. through use cases and ecosystem maps, as mentioned in section 4.2 of this paper).

Since, as mentioned, the Climaborough project is an ongoing process, this paper has to be seen as a reflection in action, that aims at starting a conversation within the design community, but also beyond it. One of the most relevant questions emerging from the experience in the Climaborough process is whether the design knowledge emerging from the process so far can be codified, replicated and become part of the diffuse design capabilities of an institution, such as a city administration, rather than being an expert design competence.

Beyond the design community, the conversation this paper could suggest would also involve city representatives, or institutional stakeholders working on urban innovation and procurement processes, in the perspective of integration of design within the existing package of legal/technical competencies that support the processes of decision making in cities.

As mentioned, this paper is the first step of an ongoing project, but it is also a possible introduction for future research and a debate related to the design capability to support the innovation processes related to the mission approach, inspired by Mazzucato (2017, 2019), that the EU is adopting to structure large innovation processes for the coming future.

KEYWORDS | CULTURAL VALUE CHAIN, MADE IN ITALY, INTANGIBLE VALUE, DESIGN-DRIVEN APPROACH, APULIAN WOOD-FURNITURE SECTOR, ECONOMICS

ABSTRACT | The research is part of 'Made in Italy circolare e sostenibile' macro-project, financed by PNRR, with the objective of promoting innovation in Made in Italy production chains. The 'New and consumer-driven business models for resilient and circular SCs' project aims to develop circular and resilient supply chain strategies to support the furniture sector. The contribution presents the first outcomes of the 'Cultural value chain. From local traditional production districts to a new country of origin effect' project, focusing on the discipline of design and its critical role in the cultural valorisation of goods. The objective is to identify a strategic design-driven approach to support the competitiveness of local production systems by valorising the identity of culture-based products and services. The concept of the *cultural value chain* emerges as an interpretative key, placing cultural value inside supply chains. The research investigates the change in the Italian manufacturing sector, emphasising the reconfiguration of industrial districts and the innovative impact of the digital revolution; in fact, the decentralisation of production phases by leader companies activates possible innovative dynamics in the industrial context and presents opportunities for micro-enterprises. In particular, the research focuses on the context of the wood-furniture supply chain in the Apulia, with a specific attention on the upholstered sector, presenting case studies to support the critical reasoning exposed. The discussion highlights the need to shift the focus towards social and cultural well-being, with design called upon to support socially sustainable enterprises. The thesis argued is that design should assume a central role in the development of new design strategies oriented towards the *cultural value chain*, considering cultural capital as a key element for the competitiveness of local production chains.

1. Introduction

The paper is part of the 'Circular and Sustainable Made in Italy' macro-project financed under the PNRR, which intervenes in encouraging the innovation of Made in Italy production chains, with particular reference to 2F Furniture and Fashion. Specifically, the project to which 'New and consumer-driven business models for resilient and circular SCs' refers deals with the research of circular and resilient supply chain strategies in order to support the Made in Italy fashion, furniture and automotive ('3A') sectors. On the other hand, the objective is to face the challenges of SMEs for a sustainable and resilient reconfiguration of global value chains by adopting strategies of re-shoring, redesigning and enhancing the cultural dimensions of local supply chains.

In particular, this contribution presents some of the outcomes of the "Cultural Value Chains: From Local Traditional Production Districts to a New Country of Origin Effect" project. The research, assuming a critical point of view, for the discipline of design, with reference to the role of the entire supply chain in the identification of the cultural value of goods, photographs the current panorama of the Apulian wood-furniture supply chain and analyses the case studies related to the context of investigation, with the aim of useful exploration for the future design of sustainable project strategies consistent with the peculiar capacities of the entrepreneurial fabric of reference.

The broader objective of the study is to identify the design-driven strategic approach to support the competitiveness of local, resilient and circular production systems, enhancing the role of the identity of culture-based products and services, also in relation to the social context and target communities. In particular, criteria are defined for locating cultural value in supply chains, in what we call the *cultural value chain* (Di Roma et al., 2024). In this chain, the cultural value generally attributed to the product is identified in the stages and actors associated with the entire process, although each stage of the entire supply chain contributes to implementing the value. The contention is that the growth of economic value in the supply chain (Porter, 1998), is also valid in cultural terms and that knowledge of the value of the product is expressed in every part in the final product.

The concept of 'made in supply chains' constitutes a paradigmatic element in the identification of the cultural capital associated with the supply chains of goods and services, finding its foundation in the complex structure of the industrial and manufacturing sector, characterised by the presence of numerous small and medium-sized enterprises specialised in various production phases, source of the considerable competitive advantage associated with the distinctive Italian territoriality (Bettiol et al., 2010; Accetturo et al., 2013). In fact, following the period of delocalisation in the 2000s, the phase of re-investment by national and international companies in the re-localisation of supply chains in their own territories has led to a reconfiguration of industrial districts that is very different from the historically consolidated one. This reconfiguration, significantly enriched by the innovative impacts of the digital revolution (Bertola et al., 2018), has been facilitated and characterised by the presence of a production structure rooted in the territory, characterised by a relevant social and cultural heritage (Porter, 1998; Berger, 2013). This phenomenon assumes great relevance with respect to recent trends concerning innovation in the manufacturing sector, considered a crucial driver of value and competitive advantage: innovation is seen as a fundamental element to improve product quality and promote customisation, as each industrial production process can generate new opportunities for learning and innovation, derived from practical experience (Bettiol et al., 2022).

In order to respond to the growing need for flexibility, the district's leader companies implement a process of decentralisation of the production phases outside, concentrating on the design, marketing and coordination of external production. A clear division of labour is thus determined, on the basis of which the commissioning companies are essentially engaged in creative activities and administrative management, while subcontractors take care of the production specialisation lines in the various phases, guaranteeing a high degree of production elasticity (Cagliano et al., 2000). The innovative dynamics occurring at the top of the industrial context can thus act as a driving force for micro-enterprises, but can sometimes also represent an obstacle or limitation to their natural growth. The introduction of complex and systemic

innovations radically transform the entrepreneurial formula and organisational model of traditional district companies, such as the regeneration of processes, the renovation of management models and the adoption of new managerial tools (Guelpa & Micelli, 2007). The difficult possibility of updating their know-how and production infrastructures in a short time, as well as the difficult access to economic measures to support them compared to industrial players, characterise small manufacturing companies. Despite the fact that innovation is one of the most efficient competitive drivers, it is considered not to be the only way in a context where the risk of leaving behind or causing micro-enterprises to fail is high.

The research, therefore, reflects broadly on the problem from an economic and political point of view as it reflects on the relationship between the local level of technical know-how and supply chain management, and cultural value. It is believed that in the context of the Italian company system, which is characterised by the capillary presence of small individual companies, in which the wood-furniture sector in Apulia is an emblematic case, it is necessary to shift the focus towards the social sphere, in work practices, as well as towards instances of innovation which, often guided by markets or politics, place these companies in a disadvantaged position. Therefore, today's design discipline has the responsibility, through oriented design, to support manufacturing companies with the construction of sustainable design strategies. These must belong to the capacitive strings of the company to adopt models and carry them forward over time, in favour of a socially sustainable enterprise.

The structure of the article, outlining this perspective, includes the general framework outlined, the analysis of the reference context and the *cultural value chain*, the focus in relation to the Apulian wood-furniture supply chain (and in particular in the upholstered product considered among the most complex and characteristic of Italian design), the enunciation of case studies drawn from the new local entrepreneurship, the conclusions and the prospects of the research.

2. Reference Scenario

The success of the 'Made in Italy' phenomenon during the 1980s and 1990s was characterised by the adoption of new organisational configurations by Italian companies across the country. These models, characterised by flexibility and resilience, were based on the division of labour between different companies operating in the same sector rather than between individual workers within the same production process, giving life to the first industrial districts (Bettiol & Micelli, 2005; Sforzi, 2008).

The national law no. 317/1991, subsequently modified by law no. 140/1999, initially defined industrial districts as homogeneous local production systems characterised by a high concentration of industrial enterprises, mainly small and medium-sized and a high degree of productive specialisation. However, an indication that reflects only two of the organisation's essential requirements such as location in a limited territorial area and reference to a specific product or production sector. It neglects two fundamental aspects of districts, namely the 'network' production model, which is based on the organic interdependence (Pyke & Sengenberger, 1991) between different companies, linked together within the supply chain (Grandinetti & Passon, 2004), and the opportunity to benefit from a relational issue characterised by the sharing of a common 'industrial atmosphere' (Marshall, 1890; 1919), that is, a shared culture and language (Marchi & Nardin, 2008). This vision of the district characterised it as an intersection between productive and social dimensions (Beccatini, 1991), facilitating inter-organisational relations, reducing transaction costs (Dei Ottati, 2003) and facilitating knowledge transfer (Camuffo & Grandinetti, 2011).

This organised strategy allowed companies to better adapt to market fluctuations by specialising and managing their production processes through collaborative networks, providing greater flexibility and operational efficiency (Becattini, 2007). The industrial district model has represented and still represents a fundamental pillar within the Italian economic system (Varaldo, 2003), having allowed small and medium-sized enterprises to develop an intense specialisation of products, then of production processes and, more recently, a redefinition of business models in a national and international context.

In this last perspective, the emergence of new countries in the global market, such as Asia, Brazil and more recently China, has led to a phase of modernisation of industrial strategies and the business model. These include the relocation of production to countries with low labour costs and the redefinition of supply networks resulting in different forms of labour organisation on a transnational scale. In this globalised scenario, we try to understand the extent to which small and medium-sized companies insert themselves into supra-local value chains, such as Global value chains (Gvc), in order to achieve long-term competitive advantage. The challenge frequently resides in the continuous development of new business ideas, creating competitive trajectories and offering strategic and response alternatives to competitors (Romano, 2004). The reorganisation of the division of labour at the global level (Ponte, Gereffi & Raj-Reichert, 2019) particularly emphasises the role of some enterprises in defining the governance of relations between Gvc actors and coordinating large-scale iter-firm networks. Many studies in the literature emphasize the positive impact that the development and upgrading of Global value chains can have on the growth of local companies and production systems in terms of employment, market development and innovation processes, encouraging upgrading processes both at company and territorial levels (Bettiol et al., 2018). However, despite the benefits of opening up to the global context, the internationalisation of activities can undermine the internal cohesion of the cluster due to the substitution of local suppliers with international ones, potentially causing leakage of knowledge and expertise at the territorial level. From this perspective, internationalisation may have a negative impact on innovation processes by separating production from innovation, an element that traditionally constituted a fundamental binomial for the success of many industrial clusters in the past.

The change required is systemic (Varaldo, 2003), since the ability of companies to relate to the external environment depends both on their operational capacity to diversify their offerings and on their strategic capacity to fit into transnational production and distribution networks. This systemic aspect is particularly relevant for small and medium-sized enterprises considering their district context that over time has made them repositories of competitive production skills and knowledge, to the point of transforming them, in recent times, into nodes of a distributed network of specialised operators beyond the local context (Micelli, Chiarvesio, Di Maria, 2010). In these enterprises, corporate intangible assets play an essential role in product, process and organisational innovation processes, distinguishing and characterising the enterprise and its offer with resources that are difficult to replicate or monetise (Romano, 2004). Image, cohesion, trust, production organisation, technological know-how, product reliability are the resources influencing the strategic orientation of the company and its identity.

In the context of the systemic context, the creation and perpetuation of organisational capabilities are based on learning processes that support the introduction of innovation. Leader enterprises are distinguished by their ability to introduce complex and systemic innovations that profoundly revolutionise the business formula and organisational model of traditional district enterprises, such as the regeneration of processes, the renewal of management models and the adoption of new managerial tools (Guelpa & Micelli, 2007). By initiating these processes of change, industrial players outline original evolutionary paths that influence the overall development of the local system towards the transition from a closed local network model to one that is more permeable to the competitive environment and interconnected with international economic circuits (Grandinetti & De Marchi, 2012). A binomial of innovations takes place, those complex and systemic innovations typical of industrial players, and the more punctual process and product innovations characteristic of the district context. Therefore, in this increasingly competitive arena, access to innovation, considered one of the fundamental pillars for business success, is not uniform between leader companies and small and medium-sized enterprises operating within production chains. Disparities in financial resources, access to knowledge networks and investment capacities create a significant gap. Leader companies, often characterised by a solid financial base and an extensive network of strategic partnerships, can afford to invest in long-term research and development, creating new technologies and advanced solutions that maintain their position of advantage in the market, as well as acquire knowledge from outside and internalise it. Furthermore, industrial players often have better access to external economic measures to support them, such as public funds or investments. On the other hand, small supply chain companies, despite their crucial role in the local economy and value chain, have difficult access to innovation due to their limited financial capacity, lack of connections, difficulty in updating

knowledge and external resources. These structural changes come within the production chains, where leader companies adopt new processes for which small companies are unable to adapt their workforce and skills. In fact, the updating of specific know-how with specialised skills and training is not easily accessible or sustainable in the short term.

The transmission and preservation of cultural knowledge represent crucial elements for the continuous evolution of the district and for the development of Italian small and medium-sized enterprises. Thus, the focus shifts from new technological innovation to that of cognitive capital and the entire organisational structure, exploiting the social human capital of the context in which it operates (Varaldo, 2003). The impact of this change influences the capabilities of the company not only in the operational phase of the production chain, but also, and above all, in many other areas, such as vision, strategies and tactics.

The research, therefore, reasons on the relationship between the local level of technical know-how and supply chain management, and the cultural value, and considers the need to shift the focus towards the entire supply chain, characterised by the capillary presence of small individual companies, towards socially sustainable business design-oriented strategies. Design must, therefore, today think about what is the longest dimension of time that can, through oriented design, support such enterprises that otherwise only have the prospect of being excluded from the possibility of following the industrial players: to build sustainable projects from the point of view of what are the capacities of the company to adopt models and carry them forward over time and with a certain degree of comfort and "well-being", in favour of a socially sustainable enterprise. New project strategies reconfigure a new concept of value, especially at a time like the current one, where innovation in a sector with a high degree of tradition is considered to be mainly associated with the result of a renewed focus on technology, towards an environment of dialogue between innovation and socio-cultural aspects.

3. Cultural Value Chain

The identification of Made in Italy (MII) as a product characterised by a high cultural value and permeated by that country of origin (Schooler, 1965), has historically distinguished the furnishing sector, connoting it with values such as attention to detail, quality of workmanship, elegance, and lifestyles referring to practices of use (Fortis, 1998), however, attributed mainly to the finished product. From an opposite perspective, which is not always effectively valorised, the MII manifests itself in supply chains and knowledge that are peculiar, distinctive and exclusive to Italy, closely connected to the territory of reference. In this context, the circular and sustainable approach to product and process innovation considers the entire chain of goods and services intermediate to the production of the finished product, such as sub-supply of materials, sub-supply of production processes, sub-supply of services, thus recognising the crucial and distinctive role of know-how historically consolidated in the territories.

To this chain, management associates a value chain (Porter, 1985) consisting of the activities that generate value in the economic sense of the amount that the end customer is willing to pay. Involving all production processes from raw materials to end use, this value is transferred and perceived in products and services, creating a competitive advantage. A value system is thus effectively created if, through the synergetic operation of actions supported by the company, an increase in profit is generated.

The research argues that the growth of economic value at each stage of the supply chain is also translated in cultural terms, coining the original concept of *cultural value chain*. The cultural value socially attributed to the product is identified in the downstream stages and actors associated with the entire process, taking a value-oriented perspective on the finished product. However, each stage of the chain is considered to contribute to the overall value of the good. In this context, knowledge of the value of the product is therefore incorporated into every part of the final product (Losciale et al., 2024). Therefore, a supply chain approach is adopted rather than an individual product approach, shifting the focus to the know-how that characterises all material processing and production steps associated with the finished product (Martinuz & Soldini, 2021). It is thus proposed to value the satisfaction of the social wellbeing of the community,

dissociating it from the exclusive objective of generating profit that does not consider the solidaristic, civil and social interests of the entire community (Mollona et al., 2021).

The expression *cultural value chain* is declined with respect to the dimensions that are responsible for creating value for the customer, considering the concept of value associated with the philosophical ideals that guide actions (Tappolet & Rossi, 2015). However, these are tangible and intangible elements on which people implicitly or explicitly base their value judgements, and thus about what they like or prefer (Figure 1). In fact, in this context, the term 'culture' refers to the values, principles, customs, practices and habits shared within a social group, in line with the contemporary design trend oriented towards the recovery of the local dimension of production, especially in traditional manufacturing contexts. This approach attaches importance to redefining the relationship with objects from a cultural perspective (Di Roma, 2020).

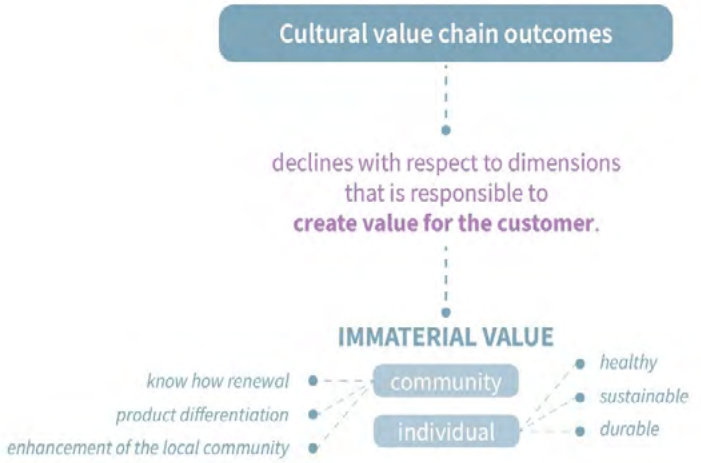

Figure 1. Cultural value chain outcomes.

The definition of the *cultural value chain* thus considers the complex relationships and social practices found in tangible and intangible artefacts (Landowski & Marrone, 2002), which thus become "cultural products" (Volonté, 2009), enriched in terms of meaning, experience, aesthetics, sharing, participation and having the role of main actors in defining the collective identity of social communities. This concept is rooted in the territory as a spatialisation of social facts (Dematteis, 1995), a mine of culture, knowledge and practices that give rise to an authentic tradition of know-how. Each territory is associated with a cultural capital understood as a "capital that incorporates, preserves and provides cultural value in addition to whatever economic value it possesses" (Throsby, 1999).

The strategies of the cultural value chain focus on implementing aspects of social and cultural sustainability aimed at preserving, maximizing, and highlighting the cultural value of a product or service across all phases of the primary production chain. Consistent with the circular economy, which promotes the efficient use of resources throughout its entire lifecycle through sustainable strategies (such as reuse and recycling), the cultural value chain operates on culturally sustainable strategies feasible in all phases of the primary production chain but which impact the value aspects attributed by users to products and thus the durability of the asset. The circular economy and the cultural value chain are both approaches aimed at maximizing the value of resources, both material and cultural, through sustainable practices and a long-term vision.

The furniture and fashion industries, including in the historical sectors of the MII, traditionally associated with the concepts of authenticity, excellent craftsmanship, high production skills and quality (Temperini et al., 2016), are therefore considered paradigmatic cases demonstrating the fundamental role played by *cultural value chains*. Specifically, these are also representative of local production systems: supply chains located in specific geographical areas characterised by the material and immaterial cultural heritage of traditional

communities of practice and relevant in the MII sectors for their characteristic production traditions, local know-how, social proximity, tacit knowledge, small business dimension, incremental innovation and flexibility of the production process (Quadrio Curzio & Fortis, 2000; Rullani, 2000; Beccatini, 1998).

Currently, as a result of globalisation processes and dramatic global events, local production systems are under significant competitive pressure (Benini, 2019; Giumelli, 2019). These systems are called to review the assumptions on which their value is based: intangible values such as knowledge, culture and creativity are emerging as sources of competitive advantage (Sbordone, 2020).

In the following section, this paper analyses the emblematic case of the wood-furniture supply chain in Apulia, demonstrating the capillary presence of small and medium-sized enterprises with a district character in the area and the need for new strategies oriented towards a *cultural value chain*.

4. Research Methodology

The research methodology included an initial phase of framing the general theme concerning the broad phenomenon of Made in Italy, with its peculiar characteristics and evolutions. Subsequently, a non-systematic but traditional literature review aims to explore and define the concept of the cultural value chain as a design-driven strategic approach to enhance the competitiveness of local production systems in Italy. In support of the proposed theoretical approach, based on the importance and uniqueness of cultural identity in Italian products and services as well as the peculiar distribution and size of local enterprises, the research proposes the macro case study of the Apulian wood-furniture supply chain, considered an emblematic example.

The research addresses the proposed case by elaborating raw data from updated reference databases (AIDA) and translating them into information, utilizing original infographics. It discusses the emergence from this analysis of the widespread presence of SMEs in the territory, a characteristic extendable to the entire Italian territory, and the challenges faced by SMEs in adapting to the dynamics of the global market. Subsequently, aware that the emerged peculiarities require ad hoc strategies accessible to the dimensions of the companies involved, it is believed that the role of design can promote innovation and sustainability in the cultural value chain. Therefore, the research aims to identify strategies that leverage cultural heritage and knowledge to create competitive advantages for Italian companies. As a result, a wide-ranging excursion into case studies in the Apulian wood-furniture sector was necessary, involving new entrepreneurship, such as startups, in order to enable thinking towards the design of such effective strategies (subject of an upcoming scientific contribution). This allows reflection on how to reference models do not come from established macro-enterprises but rather from smaller-sized ones, which support realistic and goal-oriented innovation models. The selection of case studies drew from mappings conducted in the reference territory, as presented in online reports (A.R.T.I. report, 2023), and from an exploratory analysis on traditional web search engines, also at national level.

5. The Wood-Furniture Supply Chain: The Apulian Case

The wood-furniture sector represents a complex of activities that covers the design phase, through production, to the marketing of products in an extended production chain. This chain includes both the primary sectors (wood industry for furniture and construction, production of semi-finished products and furniture components) and the subsequent sectors of the furniture industry (furniture for domestic and professional use, lighting equipment, and furnishing accessories). The wood furniture sector has shown signs of vitality and unprecedented growth over the last ten years, with a turnover of more than €478 million on international markets in 2022, an increase of 57% compared to 2019, the year before the crisis (Redazione Sistema Puglia, 2023).

The production chain, known for its marked specialisation in the manufacture of armchairs and sofas, is mainly made up of the core component, represented by the enterprises identified in "Divisione Ateco 31", relating to the "Manufacture of furniture", and some sub-categories of Group 16.2 within "Divisione Ateco 16", called "Manufacture of products of wood, cork, straw and plaiting materials" (ARTI Outlook Report, 2023).

A Unioncamere Puglia report shows a total of 3,438 companies operating in the Apulian wood-furniture sector at the beginning of 2020, of which 1,891 work in the wood industry and 1,547 in the production of furniture and sofas, with a total of approximately 18,740 employees. Contrary to what would be expected from the number of companies, it is the production of furniture and sofas that provides more employment and not wood production (12,805 people compared to 5,935 in wood) (Figure 2). For the region of Apulia, wood furniture is basically the manufacture of sofas and armchairs, with 569 companies alongside the 909 furniture production companies (bedrooms, kitchens, offices, outdoor furniture and intermediate production of parts and accessories or intermediate finishing or processing activities). Also upstream in the supply chain are the 640 building carpentry enterprises, 385 involved in the manufacture of doors and windows and 313 in wood carpentry (Figure 3).

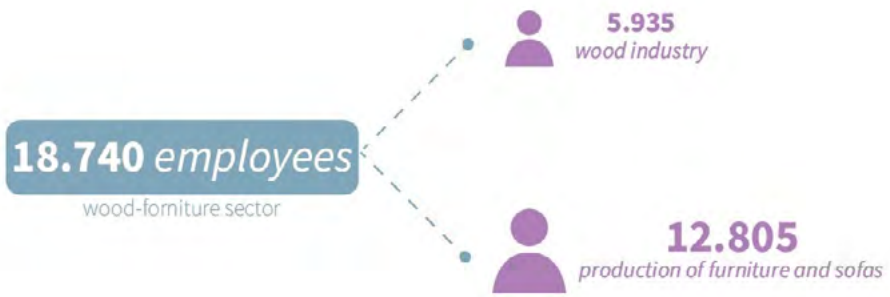

Figure 2. Apulian wood-furniture division.

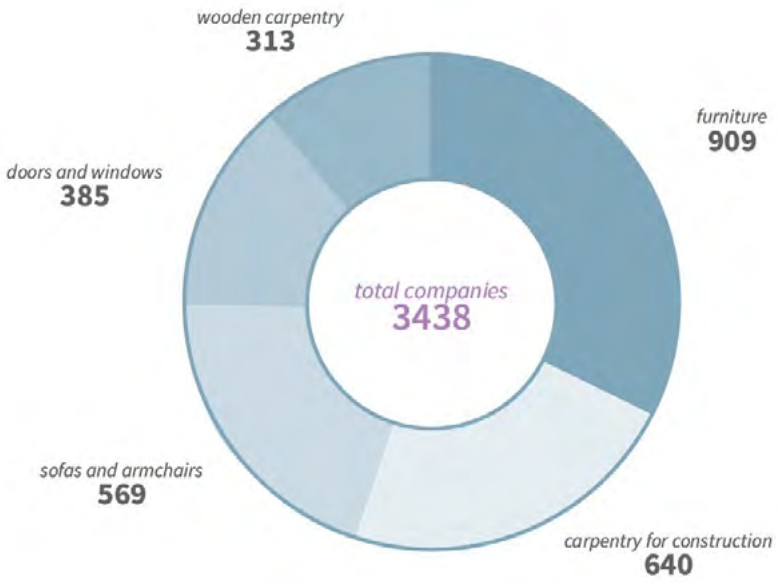

Figure 3. Division of companies by type of manufacturing in the Apulian wood-furniture sector.

Also dating back to the year 2020, the wood-furniture sector consists of 3 large companies, 22 medium-sized companies, 410 small companies and 2,992 micro-enterprises (Figure 4), which are basically represented by craftsmen and subcontractors involved in the intermediate processing of furniture factories: upholstering of living room frames or making tapestries, cutting and planing wood, manufacture of veneer sheets and panels, making wood packaging, etc.

Figure 4. Size of companies in the wood-furniture sector in Apulia (turnover and number of employees).

The Apulian supply chain shares with the national one a production offer largely made up of micro and small enterprises: in the mobile component, about 99% of the total number of enterprises in 2020, a figure substantially in line with the 98% at the national level. It is noteworthy that the greater resilience of the mobile component of the regional production chain is attributable to the positive performance of micro and small enterprises, which have shown an increase in the number of employees between 2012 and 2020. The situation at the regional level presents a significant contrast to the national average situation, which is characterised by a marked decrease in the number of employees employed in enterprises of a similar size. This trend is accompanied by a significant reduction in employment in medium-sized enterprises, while there is a significant increase in the number of employees employed in large enterprises.

The upholstered furniture sector constitutes one of the specialised segments within the wood-furniture industry. It includes the entire cycle of design, production and marketing of armchairs, sofas, seats and chairs made using techniques and materials that guarantee softness and adaptability to body shapes. This sector, within the wood-furniture industry, is configured as a supply chain characterised by several peculiarities according to the " Mappatura del settore legno-arredo in Puglia: analisi di settore e traiettorie di sviluppo, 2014" such as the relative difficulty in industrialisation, with relatively low barriers to entry for competitors, the high labour intensity and orientation towards containing production costs, the high impact of transport costs, the significant presence of both large leading companies in the sector and small and medium-sized companies generally specialised in subcontracting and sub-supplying.

In Apulia, most of the companies specialised in the production of upholstered furniture are concentrated in the Murgiano industrial district, identified by the regional administration through a study commissioned to IPRES (1999) as an area with a high specialised production vocation. According to AIDA data collected between 2019 and 2022, there are 196 companies spread over the regional territories of Apulia (163) and Basilicata (33) with a total of 5,819 employees.

From a dimensional point of view, there are 2 large companies, with a number of employees greater than 249, 11 medium-sized companies, with a number of employees between 50 and 249, 100 small companies, with a number of employees between 10 and 49, and 83 micro-enterprises, with a number of employees less than 10. Of these, most of the companies, in particular 180, have an annual turnover of less than 10 mln (144 of them even less than 2 mln), 13 companies have it between 10 mln and 50 mln and only 3 exceed the latter (Figure 5).

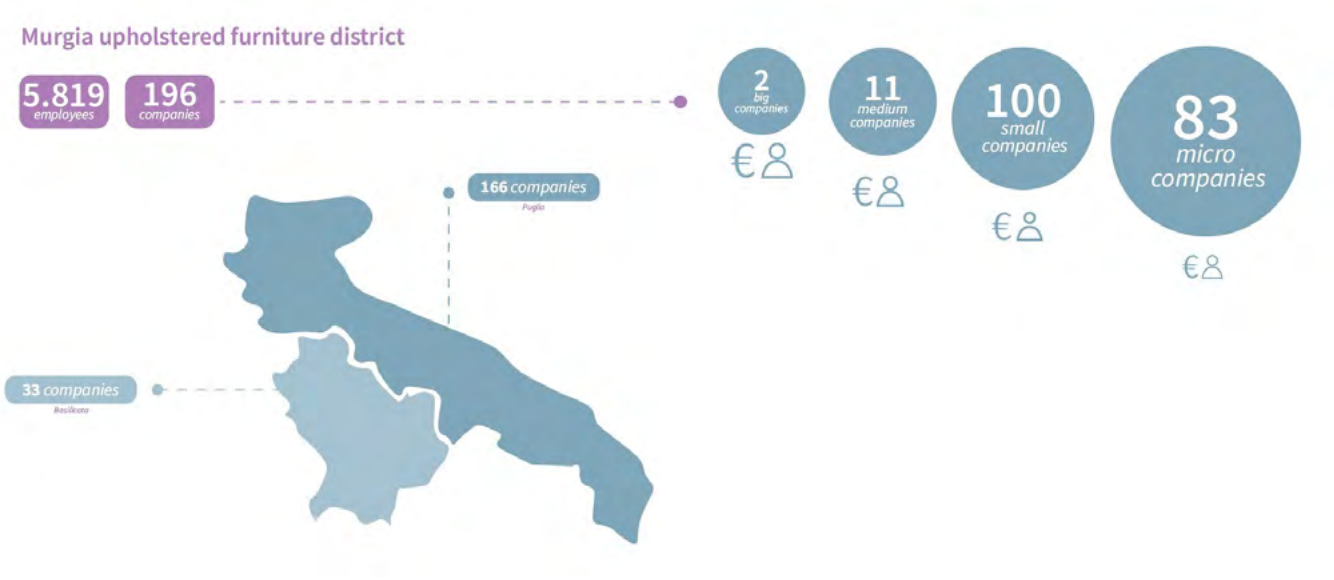

Figure 5. Murgia upholstered furniture district (location and size of companies).

The wood and furniture production chain in the Apulia region, in line with national trends, has undergone structural changes over the years that have influenced, at least in part, the sector's growth and development prospects. Some key processes that have exerted and continue to exert a significant impact include:

- For the furniture component, a relocation to Eastern European economies and then to areas outside the European Union, which have significant competitive advantages, especially in terms of lower labour costs.
- Changes in demand characteristics, with the entry of low-cost brands, including the notable impact of IKEA, characterised by distinctive style lines, affordable prices, products that can be easily assembled without assistance and innovative distribution and sales methods.
- Changes in sales channels, with an increasing presence of online trade.

Nevertheless, it is possible to detect a low propensity to innovation on the part of the sector, which is also confirmed by the marginal presence of start-ups and innovative SMEs not only at Apulian but also at national level, despite the important tax breaks and public funds specifically earmarked for them.

5.1 Case Studies

The paper broadens the exploration of case studies from new entrepreneurship, such as start-ups, in order to reflect on how the emergence of the new enterprise relates to the current state of established enterprises in the area, supporting realistic and oriented models of innovation. In addition, the reported cases were studied and selected because they enable critical reasoning about design aimed at social and environmental well-being and the enhancement of territorial and identity dimensions.

According to the WOOD AND FURNITURE report produced by ARTI (2023), at the end of the third quarter of 2023, there were only two startups in the Apulian region in the wood-furniture sector, a number that extends to 10 for the entire Mezzogiorno area and 50 for the entire Italian territory. Most of these companies operate in the furniture manufacturing sector, accounting for 50 percent of startups in Puglia, 80 percent in the Mezzogiorno and 82 percent nationwide.

Notably, Revì recovers and gives new life to furniture and furniture objects. According to the principles of the circular economy, it recovers, revitalizes, and puts products back into circulation, attributing to design the means through which to extend the life and redesign the identity of furniture and objects that would

otherwise be discarded or neglected. The project, developed by an eco-designer in the own homeland, aims to work independently, while also valuing the skills of others, without negative impacts on the environment. Fully realized in 2019, it makes each artifact unique and creates an inducement for all craft workers who contribute to the outcome. Revì is committed to recovering manual labor and revitalizing craft skills, which are in decline, by enhancing local know-how (Figure 6).

Figure 6. Artefacts from the Revì start-up [https://economiacircolare.com/dallo-scarto-alla-nuova-vita-revi-e-il-design-per-tutti/].

Legno di Puglia is the first company that uses as raw material the enormous variety of wood species that the Apulian territory offers, through the design of furniture elements. A promoter of Puglia's first wood supply chain, the company has triggered a process of enhancing the value of the tree heritage in a land that stands out for its low quantity but high biodiversity, among the highest in Italy. The start-up recovers the trunks of those trees that for various reasons are cut down and would have as their destiny only destruction and processes them to design artifacts of high craftsmanship value. In addition to the artifacts, the creation of the first Xylotheque in Italy with a regional vocation enhances and enables the knowledge and dissemination of Apulia's woody heritage through the exhibition of the different woody species (Figure 7).

Figure 7. Artefacts from the start-up Puglia Wood [https://www.legnodipuglia.com/].

On a national scale, the case studies of start-ups Wood-skin and Draw Light are considered interesting because the former empowers design thinking, and the latter focuses on stimulating awareness and knowledge through immersive technologies to promote change toward holistic wellness (although it involves the textile industry, it is believed to be assimilated to the context of interest). Through a manufacturing process patented by Wood-skin, sheets of rigid materials are modified into programmable composite materials by milling to create panels that can fold along origami-like "digital hinges." These materials can go from flat to three-dimensional form, and the process is reversible. The company produces optimized elements with minimal material waste because the production process can be studied and tested virtually: a simple assembly mechanism allows local workers to install the finished cladding themselves, limiting intermediate substructures (Figure 8)

Figure 8. Wood-skin start-up artefacts [https://wood-skin.com/products-and-services].

Get in SYNC Shade is an immersive installation designed for White Show Milan. The goal is to inform and tell, through sensory involvement, about the most polluting phases of textile production: fabric development and the dyeing and finishing phase on average account for more than 30 percent of the total impact of a garment. Get in Sync Shade was therefore preparatory to an additional sensory experience involving contact with unconventional but responsible fabrics, dyes, and fibers such as chocolate and coffee. It raises community awareness of the environmental and social impacts that certain common materials possess, stimulating change (Figure 9).

Figure 9. Get immersive experience in SYNC Shade [https://www.drawlight.net/].

6. Conclusions and Research Developments

In recent years, the analysis has revealed a weakening sense of belonging to the local and territorial community, attributed to the changes occurring in the districts, which have led to clusters characterized by a limited number of leading companies with a cosmopolitan outlook (Grandinetti & De Marchi, 2012), compared to medium-small enterprises.

The criticality of the current situation stems not only from globalization and relocation phenomena but also from the structural limitations of the district model. This inherently emphasizes the theme of flexibility, without questioning the typically industrial serial approach, with innovations and modular programs (Chiarvesio & Grandinetti, 2002) that generate moderate standardization incapable of competing with global logics (Tapscott & Williams, 2006). Subcontracting relationships among district enterprises, characterized by an exclusively productive culture, have transferred a rigid mentality that, along with dimensional, economic, and political obstacles, hinders access to innovation.

The analyzed case studies explore the current strategies proposed by startups in the wood-furniture sector to enhance cultural and territorial aspects, linked to the theorized concept of the cultural value chain. Specifically, Revì values and revives manual labor and the resurgence of declining craftsmanship skills and know-how from a product perspective. Differently, Legno di Puglia enhances the Apulian wood supply chain through the design of furniture elements with high artisanal value, as well as through the dissemination of knowledge about Apulian wood heritage through the first Xyloteca in Italy with a regional vocation. The startup Wood-skin focuses on social sustainability through digital product design, allowing local workers to install the finished covering themselves, limiting intermediate substructures. Lastly, Get in SYNC Shade, through an immersive experience, raises awareness in the community about the environmental and social impacts of some common materials.

It is believed that design today has the task of providing tailor-made design strategies for small and medium-sized businesses, spread throughout the Italian territory, enhancing their capital of experience and knowledge. To support this, the research envisages a future phase of field analysis in the current Apulian upholstered furniture supply chain, through a direct qualitative study of small businesses and their stakeholders. The research, therefore believing that sustainability is found in the valorization of the cultural value chain, is working on designing strategies that start from the knowledge of local know-how and production characteristics and develop innovative product models based on them.

KEYWORDS | CO-DESIGN SESSIONS, CHIEF DESIGN OFFICE, INNOVATION, DESIGN-ORIENTED CULTURE, EMPATHY

ABSTRACT | This article presents Workshop 2.0's findings from the Co-Design Sessions at Revigrés, a prominent Portuguese ceramic tiles manufacturer. The workshop, part of an ongoing Ph.D. research, was held in March 2023, and involved stakeholders from industry, retail, and research. It tested assumptions about the Chief Design Officer's (CDO) strategic role in evolving a company's product range, educating stakeholders about design value, and enhancing creativity through open communication and collaborative activities. Aligned with design thinking principles, Workshop 2.0 focused on "kinetic tiles" and "smart tiles" themes, aiming to envision innovative ceramic products to position Revigrés as an industry leader.

Facilitated to nurture creative freedom and diverse perspectives, the workshop emphasized empathy, user-centricity, and creative problem-solving. The practical outcome included the ideation phase of four ongoing project proposals.

The hypothesis suggests that design thinking is a potent tool for meaningful connections between brands and users, fostering brand loyalty and innovation rooted in real-world needs. A well-implemented design function cultivates collaboration and creative problem-solving, essential in today's evolving business landscape. Workshop 2.0 exemplifies design thinking's role in shaping a design-oriented culture guided by a CDO for innovation at Revigrés. It highlights the collaborative nature of design thinking as a common practice employed by CDOs, mediating between design and business objectives. The workshop explores empathy, innovative solutions, and a transformative mindset as key elements fostering a culture of design-driven innovation at Revigrés. As Revigrés continues its co-design journey, Workshop 2.0 serves as a visionary experiment offering insights for innovation and design excellence.

1. Introduction

1.1 Building Design-Led Innovation at Revigrés: A Journey of Co-Creation

This study fits into the scope of ongoing Ph.D. research led, aiming to explore and affirm the role of a Chief Design Officer (CDO) in a corporate environment, having Revigrés as a platform for strategic experimentation.

In the prototyping length of the Ph.D. research, a series of four co-creation design sessions were organized by the research team, engaging various stakeholders from industry, retail, and research fields. Under the format of workshops, they were designed with a focus on innovative product development, and leveraged design principles, techniques, and methodologies to explore two distinct themes within the context of Revigrés, a prominent Portuguese manufacturer of ceramic tiles. The overarching goal of these sessions was to experiment with how to drive design-led innovation and to show the potential strategic role of a CDO within the company. Held between January and May 2023, in three different locations, these workshops aimed to test key assumptions, foster a design-oriented culture, and develop groundbreaking concepts that could shape Revigrés' future product range.

Since these activities are part of a study in which the goal is to assert the CDO role in businesses, the research team approached the workshops with specific assumptions to validate. Previous studies and activities such as case studies and interviews have shown some practices applied in the design function of companies like Philips, 3M, PepsiCo, and J&J, led by CDOs [1; 2; 3]. The inputs gathered in these studies and the literature review prompted several research questions and hypotheses that have since been tested by the research team.

The first assumption aimed to explore how the CDO's strategic responsibility for evolving the product range could lead to more creative solutions and broaden the company's offerings. The second assumption examined whether the CDO's role in educating stakeholders about the value of design would enhance their understanding of the design function and its activities. The third assumption sought to determine if open communication with multidisciplinary participants in the design process could improve creativity and lead to more innovative concept generation. Finally, a fourth assumption delved into the challenge of embedding and scaling up a design culture within the organizational context, making it a key goal for the CDO.

Furthermore, in the organizational context of Revigrés, the Co-Design Sessions emphasized two central themes devised by the research team. The first theme focused on the development of kinetic energy ceramic tiles, exploring how this technology could enhance the product range and boost the company's innovative performance. The second theme, centered around "smart tiles," sought to envision new products, services, and experiences integrated into intelligent ceramic tiles that optimize spaces and fulfill multiple functions. These themes emerged from the research team's design vision to develop multi and plural-function products for Revigrés, as a catalyst of innovation aligned with the strategic guidelines defined to implement a design function within the business environment.

These themes embedded in the Co-design sessions were aligned with the assumptions related to the leadership role of the CDO. Specifically, they test how to rapidly prototype to expand the company’s offerings and range of products through design-led processes and innovative concept generation. The construction of the sessions also aimed to educate stakeholders about design processes by incorporating design thinking tools and mindsets into the equation. This approach aimed to achieve quick concepts within the four sessions, ultimately leading to a showcase of the value that design can bring to a company. As a strategy, the overarching goals of this Co-Design Sessions initiative were threefold. Firstly, the research team aimed to build design-oriented innovation processes for Revigrés, ensuring that design played a central role in driving innovation within the company. Secondly, the team sought to explore the implementation of design culture within Revigrés, fostering a mindset of creativity, collaboration, and user-centered thinking. Thirdly, the initiative aimed to develop a range of concepts for innovative multi and plurifunctional products that would position Revigrés as a leading player in the market.

The research team anticipated gaining valuable insights into the impact of collaboration, multidisciplinary practices, and design thinking on product innovation at Revigrés. Specifically, it is projected that the set of workshops establishes an approach to demonstrate the importance of collaboration and multidisciplinary approaches in the creative process. By bringing together stakeholders from various backgrounds, the research team intended to showcase the transformative impact of incorporating design thinking methodologies into project and corporate development. Through a co-creative design-driven process, the workshops were dedicated to developing the concept of “kinetic tiles” and "smart tiles." It’s anticipated that the sessions capitalize on a wide range of know-how and perspectives by involving stakeholders with diverse expertise.

Observations and feedback gathered during the sessions were expected to provide significant contributions to the understanding of creative processes and design culture. Ultimately, the workshops were envisioned to yield two or more distinct product concepts, arising from collaborative processes with various stakeholders. These concepts were intended to form the foundation for potential final products, showcasing the CDO's contributions through both a contributory structure, guided by designers and specialists, and a collaborative structure, driven by all stakeholders. Additionally, the research team intended these sessions to be a vehicle for the application of new design-led innovation processes within the organizational culture at Revigrés, fostering a transformative design-thinking culture that permeates the entire company.

2. Research Methodology

This study explores the experimentation of a process of building design-led innovation at Revigrés through a journey of co-design and multidisciplinary workshops, according to the following research methodology. The co-design sessions were promoted both within the university where the doctoral research undergoes and within Revigrés. The workshop promotion included a detailed description of the objectives of the co-design sessions, the specific objectives of each workshop, the agenda, duration, location, and facilitators' descriptions.

For the university participants, enrolment was open to students, teachers, and researchers from any course or degree. The workshop had a limited capacity of 15 seats and the selection process was based on a first-come-first-served basis. The aim was to encourage a diverse range of perspectives and expertise among the university participants.

For Revigrés’ employees and stakeholders, the remaining half of the workshop seats were reserved. The selection process for this group was based on nominations and recommendations from the company's management to ensure representation from different departments and roles within the organization.
The research methodology adopted a mixed-methods approach, integrating qualitative and quantitative data collection methods to gather comprehensive data on the impact of design thinking and the role of CDOs in enhancing the innovation process within the company. Data was collected through participant observation, feedback surveys, and interviews.

The research applied a sequential exploratory strategy, which involved an initial qualitative phase (participant observation, document analyses, and interviews) followed by a quantitative phase (feedback surveys) to corroborate the qualitative findings. This approach allowed for a holistic understanding of the co-creation process and the participants' perspectives. The main data collection methods were:

- Participant Observation: participant observation was conducted during the co-design sessions to capture real-time interactions, collaboration, and problem-solving processes among the participants. This method allowed the researchers to immerse themselves in the co-creation environment, facilitating and gaining deep insights into the dynamics of the workshops, the facilitation process, and understanding the participants' experiences and interactions.

- Interviews: Semi-structured interviews were conducted with some participants, including Revigrés' employees, students, researchers, and workshop staff, to gather in-depth insights into their perceptions, experiences, and learnings from the co-design sessions. These interviews explored participants' attitudes toward design thinking and the impact of the workshops on their creative thinking.
- Feedback surveys: post-workshop surveys were administered to assess participants' satisfaction with the co-design sessions, the effectiveness of the design thinking methodologies, and their perceptions of the value of design-led innovation at Revigrés. Questions like "What worked well?", "What could be improved", "Ideas?" and "Questions?" were set.
- Document Analysis: Documentation of the co-design sessions, including canvases, brainstorming results, and prototype designs, was analyzed to identify themes, patterns, and innovative concepts that emerged from the workshops. Document analysis provided valuable qualitative data that complemented the interview and survey findings.

Qualitative data from participant observations, interviews, and document analysis were analyzed. The data were transcribed, coded, and categorized into themes and patterns, capturing participants' experiences, challenges, and creative outputs during the co-design sessions. The quantitative data from feedback surveys were analyzed using descriptive statistics, providing insights into participants' overall satisfaction and perceptions of design thinking methodologies.

Triangulation was employed to ensure the validity and reliability of the research findings. Data triangulation involved cross-verifying information from multiple data sources, including participant observation, interviews, surveys, and document analysis. The convergence of findings from different data collection methods added credibility to the research outcomes and was converted into infographics to be communicated to the company and design community.

Ethical considerations were given due importance throughout the research process. Informed consent was obtained from all participants before data collection. Anonymity and confidentiality were ensured to protect participants' privacy and identities. The study complied with the ethical guidelines outlined by the company ethics board.

The research faced some limitations, including a significant diversity of participants, which may limit or influence the generalizability of findings. Additionally, the four-hour duration or even the different participants per challenge of each co-design session may have constrained the depth of insights that could be obtained. Nevertheless, efforts were made to mitigate these limitations and draw meaningful conclusions from the available data. Each workshop data analysis helped to improve the next one, contributing to a continuous improvement in the facilitation procedure and in the session structuring.

3. Empathy in Design: A Multifaceted Exploration

Over the past decade, Design Thinking has emerged as a catalyst for fostering innovation and creativity, particularly in addressing complex, "wicked" problems and driving product and service innovation [4;5]. Central to the potency of Design Thinking is its unique ability to harmonize the desirability experienced by users with the economic viability and technical feasibility of innovative ideas [6]. Design Thinking leverages rapid prototyping, abductive reasoning, and empathy as propelling forces for generating innovative outcomes.

The discourse on empathy in design spans 50 years, with a recent intensification over the last quarter-century. Defined as the ability to perceive the world through others' eyes and feel what they feel [7;8], empathy holds a pivotal role in human-centered design processes. The empathize stage in Design Thinking mandates a collection of experiences, insights, and observations to establish a robust foundation for subsequent design phases.

Empathy, as elucidated by IDEO [9], transcends mere understanding; it involves a profound grasp of the problems and realities faced by the target audience. It necessitates learning about their challenges, latent needs, and desires, emphasizing the importance of understanding their environment, roles, and interactions.

The historical evolution of empathy, as detailed by Lanzoni [10], reveals shifting meanings across disciplines. The methodological incorporation of empathy into design has emphasized explicit cognitive and affective efforts to interpret users' perspectives [11]. Designations such as “complex” [12;13], “re-enactive” [14], or “higher-order” [15] empathy highlight its interpretive and reflective forms.

In the realm of design responsibilities, empathy aligns with beneficent and egalitarian design, often associated with democratic approaches like Co-design and participatory design [16;17;18]. Linked to care work and ethics [19], empathy fosters inclusivity, especially where diverse needs are poorly met by standard features [20].

Empathy proves integral to product and service relatability and sustainability [21; 22]. In business solutions, it becomes a strategic component for remaining relevant in the market, preventing the creation of solutions that miss the mark [23]. Across this angle, in design processes, empathy operates as both a tool for designing and a means of gaining insights into users' needs [24]. Design Thinking, as a collaborative approach, naturally integrates participants' empathic insights into the process, fostering social sensitivity [25].

Despite varied definitions, empathy in design is methodologically perceived as a deliberate and reflective tool. Recognizing its passive dimension elucidates its foundational, automatic role before becoming an intentional activity. For effective design methodologies, emphasis on the passive side of empathy is crucial, understanding that it operates tacitly before becoming a consciously intended activity enabling reflective and imaginative techniques for user research and concept development [26].

In inference, the multifaceted exploration of empathy in design reveals its indispensable role in fostering innovation, inclusivity, and user-centered solutions within the design thinking framework. Understanding its nuanced dimensions and embracing both its passive and intentional facets enriches the design process, ensuring a clearer view of how empathy operates and can be harnessed in design practice.

4. Workshop 2.0: Nurturing Creativity through User-Centered Design

The second workshop in the Co-design Sessions series marked a crucial juncture in the journey toward design-led innovation at Revigrés. Held on the 22nd of March at Aveiro University, this workshop strategically bridged the gap between the inspirational spark ignited in Workshop 1.0 and the concrete prototypes that would take form in Workshop 3.0. In Workshop 2.0, the mission was clear: to delve into the world of ideation, with a keen focus on understanding users and the contexts in which they interact with products, services, or experiences.

Particular emphasis was placed on cultivating empathy among participants, turning it into a cornerstone for ideation. Empathy in this context goes beyond mere sympathy; it entails immersing oneself in the user's world, understanding their perspectives, and feeling their needs. Despite the workshop's short duration, this approach underscores the criticality of thorough user research in design projects. The workshop emphasized the imperative for designers to immerse themselves in users' needs, aspirations, and challenges.

Workshop 2.0 employed immersive activities to encourage participants to envision scenarios from the users' perspectives. Its foundation was laid in Workshop 1.0, where participants were introduced to the main themes and framed proposals, serving as inspiration for this session [27].

4.1 The Attendees

Anchored in the larger mission of design-led innovation, Workshop 2.0 laid the groundwork for transformative product development and was a dynamic convergence of minds, drawing participants from diverse backgrounds. This cohort included 16 individuals who brought unique perspectives and expertise to the table. Among them were students, educators, and researchers spanning a multitude of academic disciplines. Complementing this academic cohort were Revigrés employees, representing various facets of the company's operations. This eclectic blend of participants formed the very bedrock of Workshop 2.0, guaranteeing a rich spectrum of insights and experiences.

Participants were thoughtfully grouped to ensure equitable representation across various dimensions, including the gender balance, with an equal distribution of 50% male and 50% female participants, as shown in Figure 1. Furthermore, these groupings considered different areas of expertise, thereby reflecting a comprehensive cross-section of knowledge domains. The represented areas spanned the realms of design, sea sciences, commercial operations, material engineering, production, logistics, financials, product management, quality, and R&D.

Team configurations mirrored the themes explored in the Co-Design Sessions and reflected the diversity of proposals generated during Workshop 1.0. In teams A and C, the Smart Solutions challenge took center stage, while teams B and D embraced the Kinetic Tiles challenge. These teams retained the same names as the proposals that had emerged from Workshop 1.0, even though the composition of team members had changed.

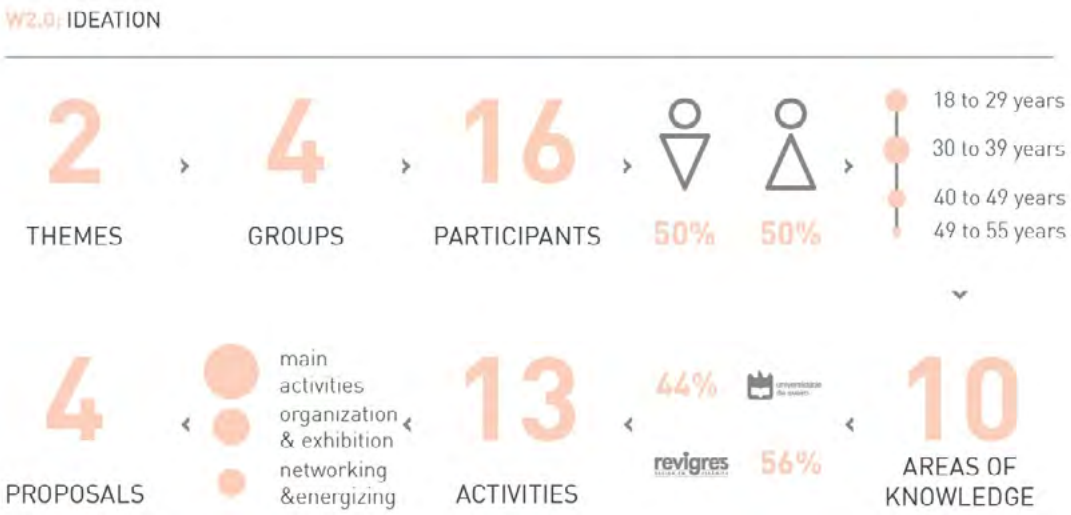

Figure 1. Workshop 2.0 in numbers (source: authors).

4.2 Program and Methodologies

Workshop 2.0 adhered to a well-defined schedule to ensure optimal utilization of time and resources as illustrated in Figure 2. The workshop spanned a focused four-hour duration, with each phase meticulously structured to facilitate the exploration of user-centered scenarios and the application of design methodologies.

To initiate the workshop, participants were greeted with an introductory presentation. The facilitator, a member of the research team, set the stage by providing context about the Ph.D. project and the objectives of the Co-design Sessions. This initial presentation offered participants a clear understanding of the workshop's scope and objectives. A concise definition of design thinking methodologies and a set of workshop rules set the foundation for creative exploration with a design mindset. These rules included directives like staying focused on tasks and time constraints, ensuring that all voices were heard and respected, and emphasizing active participation and recording of ideas. The aim was to encourage a mindset of exploration, experimentation, and learning, fostering a space where all participants felt

comfortable and confident in sharing their ideas without hesitation, even seemingly unconventional ones. Following an engaging Superpower Icebreaker activity was led. This exercise aimed to break the ice and introduce participants to the group. Each participant was given a card and a colored marker and asked to create a superhero persona, complete with a name, superpower, and visual representation. This activity set a creative tone for the workshop.

After group formation, at their respective tables, participants immediately gained access to a card detailing the initial challenge and the proposal relevant to their group. Participants spent approximately 10 minutes analyzing and discussing the proposal description that had emerged from the previous workshop. Subsequently, participants embarked on a structured brainstorming session using the Ox tool [28]. They were tasked with understanding their assigned proposal, defining its purpose, target audience, and potential development and implementation methods. This ideation process encouraged participants to think critically about their proposals.

To maintain enthusiasm and stimulate creativity, a dance-based energizer activity was employed, playing a vital role in keeping participants engaged and motivated throughout the workshop.

Participants were dared to create personas aligned with their challenges. Using a canvas, participants defined persona traits, created visual representations, crafted biographies, identified expectations, needs, and frustrations, and even gave their personas a voice. This exercise promoted empathy and a deeper understanding of potential users.

To avoid fatigue a diverse and engaging coffee break was set, allowing participants to recharge, interact, and network. This break provided a conducive environment for informal discussions.

Afterwards, scenarios were generated using the AEIOU methodology [29]. Participants defined scenario elements, including activities, space, interactions, and objects, and their relationships with users using the materials offered. This structured approach enabled teams to transform their ideas into tangible scenarios. The Six Thinking Hats methodology was followed, aiming to help participants generate ideas considering the personas and scenarios previously created. Participants donned different "hats" representing distinct thinking perspectives (white, green, red, blue, yellow, and black). Each perspective encouraged diverse thinking about their proposals, fostering the generation of creative solutions [30].

After this exercise, each group had the opportunity to present their generated ideas and inputs achieved during the workshop to all participants. This phase allowed for the sharing of concepts and provided a platform for feedback and discussion among participants.

The workshop concluded with a feedback session, where participants reflected on the activities and shared their thoughts. An after-work drink offered an informal setting for further networking and discussions. This feedback loop was essential for refining future workshop sessions and improving the overall design process.

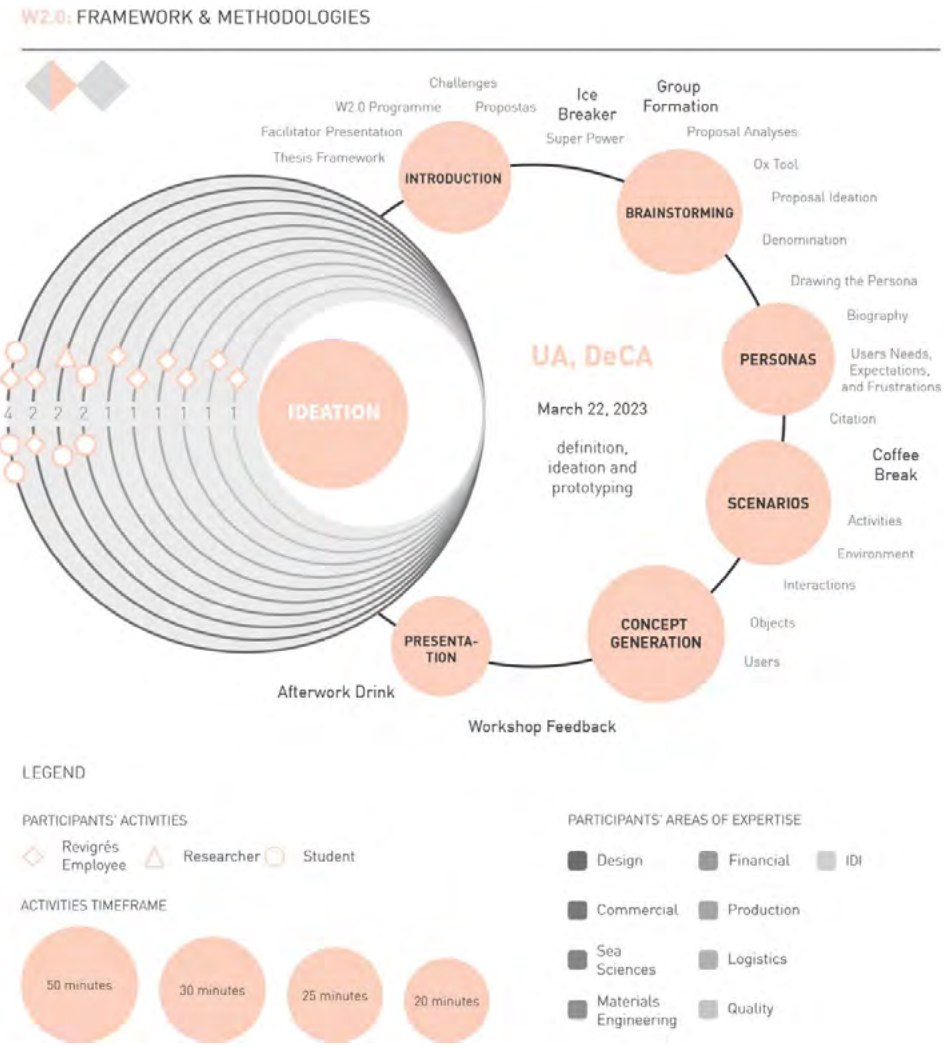

Figure 2. Workshop 2.0 framework and methodologies (source: authors).

4.3 Space Organization, Ambiance, and Materials

The spatial organization of Workshop 2.0 was purposefully curated to stimulate creativity and facilitate immersion in design methodologies. The chosen classroom at Aveiro University, with its proximity to the department overseeing design curricula, was a strategic choice. This location not only provided an ideal setting for ideation but also embodied the workshop's commitment to the principles of design. Inspirational visuals adorned the walls, serving as catalysts for creative thinking and imaginative exploration.

An array of selected materials was thoughtfully provided to catalyze the ideation process. Over 600 Playmobil figures, including human and animal figurines, were available to participants, enabling them to craft dynamic and interactive scenarios. Additionally, a rich Playmobil collection of scenery components spanning living rooms, bedrooms, kitchens, bathrooms, outdoor spaces, markets, operational machines, workshops, and factory tools, offered a rich tapestry for scenario construction. These materials were carefully arranged to encourage participants to blend and adapt pieces to construct their own unique interpretations of the scenarios.

Further, 150 rectangular cardboard pieces were available, which, when folded, formed hats. In addition to this, 16 canvases, one for each group, were supplied for exercises such as brainstorming, personas, scenario generation, and the six thinking hats exercise. A card containing the Co-design session themes and proposal descriptions was distributed to each group from the outset, tailored to their specific theme and proposal. Plus, 24 small cards were provided, each describing the characteristics of the hats in the Six Thinking Hats exercise, facilitating idea generation.

This selection and organization of materials created an environment where participants could unleash their creativity and explore innovative ideas in a structured yet open manner.

4.4 Workshop 2.0 Core Activities: Exponentiating Empathy and Critical Thinking

Workshop 2.0 marked its commencement with a crucial exercise aimed at facilitating a profound comprehension of proposed ideas and their target audiences. The principal objective was to elucidate the rationale underpinning each proposal, its intended beneficiaries, the potential for development, and the strategies to accomplish it. This exercise was allotted 25 minutes, underscoring the centrality of ideation within stringent time constraints.

During this phase, workshop participants embarked on a collaborative journey of ideation, steered by what the OX Tool [28]. This tool was designed to establish a comprehensive perspective of each proposal. Participants engaged in a rigorous and structured discussion, addressing the tool's predefined queries, encompassing the "why", "how", “with whom”, and "for whom" dimensions of the proposal. This multifaceted exploration entailed a comprehensive exploration of the proposal's purpose, feasibility, anticipated benefits, and distinctive attributes. Participants probed into the reasoning behind the proposal's potential effectiveness and the logistics to execute it. This encompassed delineating requisite tools and resources.

Participants cultivated an understanding of the proposal's target users, by scrutinizing the users' tasks, areas where the proposal could aid, and the associated pain points and challenges. This inquiry illuminated user needs, and aspirations, grounded in benefits and challenges.

The exercise also considered potential collaborators and partners, including external entities and pertinent Revigrés departments, which might play pivotal roles in the proposal's realization.

The comprehensive knowledge garnered during this phase was essential in laying a solid foundation for subsequent design and development phases. Additionally, participants were encouraged to utilize visual aids, such as drawings or low-fidelity prototypes, to effectively communicate their ideas within the group. Subsequently, the workshop introduced the Personas methodology, reinforcing the significance of comprehending users and cultivating empathy. Workshop participants were tasked with defining representative user profiles pertinent to their assigned proposals, thereby establishing a profound connection with these personas to engender more impactful solutions. This exercise was accorded 25 minutes, allowing participants to immerse themselves in the creation and exploration of user personas. The structured approach encompassed several key steps: defining general traits, “drawing” the persona, shaping a biography, and quoting them. Throughout the exercise, participants were reminded that this process was dynamic, with elements influencing each other. The numbering of the steps in the canvas merely served as a guide, allowing flexibility within the exercise structure.

While this exercise fostered a deep understanding of users and their needs, it was crucial to realize that comprehending the design proposal should go beyond users. It should encompass the broader context, including the interactions between users, activities, environments, interactions, and objects [29]. This underscores the importance of constructing scenarios, the third core exercise of this session. The overarching objective was to empower teams unfamiliar with the design process by leveraging the AEIOU tool, which provided structure and guidance This exercise was time-constrained, allocated to a 20-minute time frame to encourage efficient knowledge gathering and scenario construction that holistically incorporated user experiences.

Participants commenced by delineating scenario elements: activities, environments, interactions, objects, and users. They analyzed activity sequences, spatial characteristics, interaction dynamics, object impact, and user roles. This process unveiled the scenario's complexities, prompting inquiries into user motivations and needs.

Simultaneously, participants commenced the construction of the scenario, placing it at the center of the canvas. This visual representation was facilitated with Playmobil figurines and scenario pieces, lending a tangible dimension to the visualization of the scenario's key components.

The latter part of Workshop 2.0 beckoned participants to venture into solution and decision space, initiating a phase of collaborative ideation. This phase relied on Edward de Bono's Six Thinking Hats methodology, renowned for its capacity to stimulate innovative idea generation by encouraging problem-solving from six distinct yet complementary perspectives. This methodology is extensively employed in design leadership and various corporate and problem-solving contexts, since it harnesses different modes of thinking, offering a systematic approach to arrive at effective conclusions efficiently [30]. The scientific basis of this technique introduces structured thinking into group discussions, countering unstructured and biased thinking, which often leads to irrational decisions and favoritism toward specific ideas [31].

Likewise, the methodology advocates parallel thinking, where team members collectively focus on specific aspects of an issue, ensuring systematic consideration of diverse perspectives. It assigns specific thinking roles, symbolized by colored "thinking hats." Each thinking signifies a unique approach [30], depicted in Figure 3.

This exercise unfolded over 50 minutes, comprising specific stages for each thinking hat. Since each thinking hat represented a distinct mode of problem-solving, it ensured a structured and comprehensive exploration of ideation and idea generation.

This structured approach emphasized adherence to allotted times for each stage, fundamental to the exercise's success. It also encouraged participants to document their thoughts to expedite the process. Notably, all participants donned the same thinking hat (thinking approach) simultaneously, minimizing personal biases and conflicts. The exercise unfolded through structured stages, promoting diverse thinking and collaborative problem-solving. This approach offered participants a systematic framework to explore the proposal's problems comprehensively, stimulate creativity, and analyze both benefits and risks, ultimately leading to well-rounded and innovative solutions, which resulted in a set of ideas to be pursued in workshop 3.0.

Figure 3. Six Thinking Hats methodological structure applied in Workshop 2.0 (adapted by the authors).

5. Insights Gained from Workshop 2.0

Building upon the foundational sparks ignited by Workshop 1.0, Workshop 2.0 served as the fertile ground where inspiration metamorphosed into tangible ideas through a meticulous exploration of users and contexts. The workshop was governed by directives emphasizing focus, time management, and inclusivity, fostering an environment conducive to experimentation, exploration, and learning. The main insights achieved in this workshop were “Empathy as a Central Driver of Innovation”.

Empathy as a Central Driver of Innovation

Empathy emerged as the keystone of innovation during Workshop 2.0, substantiating its indispensable role in the design process. The personas exercise, deeply rooted in design thinking principles, facilitated a profound comprehension of users that transcended conventional demographic boundaries. This empathic approach, as advocated by design scholars like Brown [5], Liedtka and Bennett [32; 33], reached beyond surface-level user needs, delving into their motivations, aspirations, and challenges. The personas exercise not only provided a practical tool but emphasized empathy as a pragmatic necessity in designing products intricately attuned to human experiences.

Even though it is recognized that to be effective this exercise needs to be deeply explored, the exercise unfolded with a fluid, non-linear dynamic, enabling participants to adapt persona profiles as necessary. This malleability allowed for nuanced storytelling based on action, enriching the understanding of personas' experiences and interactions. Furthermore, the integration of personas in group projects brought a human touch to the design process, ensuring technical solutions resonated with users on a profound level.

Decision-Making Dynamics in the Process of Innovation

Design thinking, intricately woven into Workshop 2.0, provided the methodological scaffold for innovation. The Six Thinking Hats methodology, a prominent tool, showcased its applicability in design strategy. Drawing from Bono’s [30] insights, the methodology fostered collaborative thinking, systematic problem-solving, and diverse perspective exploration boosting the decision-making process. This methodology encourages participants to metaphorically put on different hats, representing various lenses of analysis applied to a single problem, opportunity, or challenge.

Drawing from design leadership literature, particularly from Boland and Collopy [34], the methodology's impact on collaborative thinking, innovation stimulation, and conflict resolution aligns seamlessly with the demands of managing design processes, strategies, and teams through technology-enabled systems. In the context of Workshop 2.0, the Six Thinking Hats methodology not only streamlined collaborative efforts but also enhanced the decision-making process by offering a structured approach to problem-solving. The method encourages participants to view challenges from different angles, promoting objective thinking and minimizing counterproductive interactions. This approach not only ensures efficiency but also addresses conflicts inherent in design teams, leading to well-rounded evaluations and, ultimately, significant outcomes. As a crucial tool in the design leader's arsenal, the Six Thinking Hats methodology exemplifies how different perspectives can imprint various reactions in decision-making, a fundamental aspect of strategic design leadership. From a facilitator's standpoint, this approach proved to be instrumental as highlighted by the participants in workshop feedback uncovered in Figure 4.

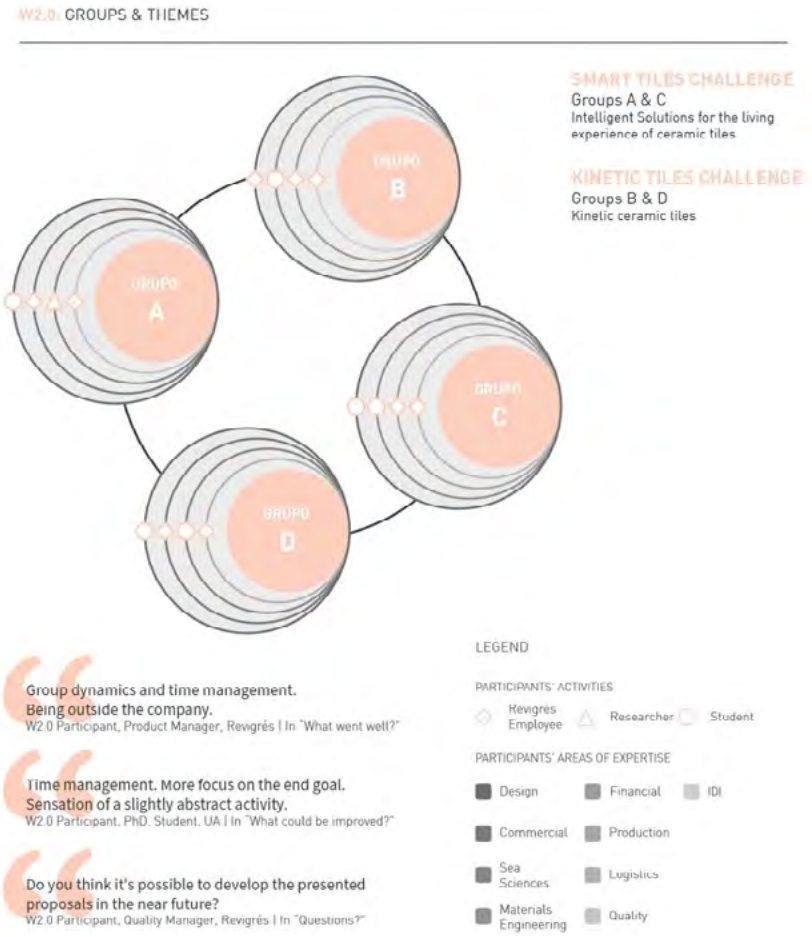

Figure 4. Workshop 2.0 group structure and participants' feedback (source: authors).

Holistic Approach of Design in Innovation

The holistic approach surfaced prominently in Workshop 2.0, extending beyond technical considerations to embrace societal, economic, and environmental implications. This holistic perspective, harmonized with multidisciplinary collaboration, aligns with design scholars like Cross [35]. Analyzing users and constructing scenarios showcased how a multifaceted examination enriches the design process. This holistic view resonates not only in the design domain but also reverberates in the strategic role of CDOs within organizations. A CDO, as a strategic leader, should integrate this comprehensive approach into the company's ethos, addressing design as a key player in business strategy and innovation [36].

Within the course of the workshop, all groups demonstrated a holistic approach to their projects, considering not only the technical aspects but also broader societal, economic, and environmental implications. Several scenarios crafted by the groups went beyond the immediate technical application of the ceramic products. They considered how these products would fit into and enhance users' lives, creating a more enjoyable, sustainable, and efficient lifestyle. This goes beyond functionality to address the emotional and experiential aspects of design. This holistic perspective is crucial in the field of design, especially when proposing innovative solutions that are intended to have a real-world impact. It reflects an awareness that a successful design isn't just about the product itself but also about how it fits into and transforms the larger ecosystem.

Creating and Aligning Values to Innovate

The imperative of aligning project values with societal, economic, and business values emerged as a guiding principle in Workshop 2.0. Market viability, a central concern for businesses, was ingrained in the analytical fabric of the workshop. Sustainable innovation, responding to global trends and crises, unfolded organically

in the projects, underlining the contemporary emphasis on environmentally conscious practices. Global applicability, another facet explored, aligns with the strategic goals of internationalization, a pursuit often integral to companies' growth strategies. The workshop revealed that creating and aligning values is not just a design consideration but a strategic move that resonates with the *zeitgeist*, emphasizing the profound impact design can have on business and society [37].

During the workshop, group questions and considerations delved into market feasibility, technology readiness, and economic viability indicating a pragmatic awareness of the challenges in implementing innovative solutions. This business-oriented thinking is crucial in ensuring that the proposed designs are not just creative exercises but have a practical pathway to implementation and success in the market. All groups showcased a commitment to sustainable innovation. Whether it was in developing tiles with clean energy-generating capabilities, reusing water vapor in manufacturing processes, or promoting a circular economy, the projects aimed at advancing not just product innovation but also sustainable and environmentally conscious practices in their respective domains.

The recognition of the international scale in project indicates an understanding of the global nature of design and innovation. It suggests that these projects are not confined to local contexts but are envisioned to have applicability and impact on a broader, potentially global, scale.

The Strategic Role of Facilitators in Workshop 2.0

Workshop 2.0 at Revigrés brought forth a crucial insight into the role of a facilitator in steering multidisciplinary groups toward a design-led process. The intricate dance between aligning values and workshop goals with diverse participant perspectives emerged as a cornerstone for success, akin to aligning society values with the goals of a corporation. The challenge lay in harmonizing the diverse thoughts of participants, each carrying their professional and disciplinary nuances, into a coherent and purposeful design narrative.

The workshop emphasized the paramount need to instill empathy among participants. Facilitators played a pivotal role in fostering an environment where participants shifted from a mindset of rapidly seeking solutions to a thoughtful contemplation of users' needs. This shift, though fundamental to design thinking, proved challenging, highlighting the resistance to moving beyond conventional problem-solving approaches. Participants needed guidance to navigate this mental shift, showcasing the facilitator's influence in shaping mindsets toward a user-centric approach.

Moreover, the difficulty in encouraging participants to view projects holistically became apparent. The innate inclination to focus on specific aspects or individual contributions hindered a comprehensive understanding of the project's broader impact. Facilitators, acting as orchestrators, skillfully guided participants to embrace a holistic perspective, linking diverse elements into a coherent and impactful design strategy.

The facilitator's role extended beyond guidance—it was about creating a well-organized workshop ecosystem. This structure incentivized dynamic and proactive ideation, steering participants away from siloed thinking. A well-orchestrated workshop, much like a well-structured company, cultivates an environment conducive to collaboration, innovation, and adaptability.

6. Discussion

Workshop 2.0 at Revigrés emerged as a crucible for testing the fundamental assumptions and hypotheses integral to the Co-design Sessions' overarching goal — affirming the strategic role of a CDO. This workshop, strategically positioned between inspirational ignition and tangible prototype creation, provided profound insights into the dynamic interplay of design leadership and facilitation.

The Co-design Sessions sought to understand how a Chief Design Officer could strategically steer the evolution of a product range, educate stakeholders about design value, and foster open communication for enhanced creativity. Workshop 2.0 unveiled the intricate dance of the CDO as a design leader. The methodology grounded in design thinking principles validated the hypothesis that design thinking is not just a methodology; it's a potent tool for establishing meaningful connections between the brand and users. The CDO, as a proponent of design's value, emerged not merely as an educator within the company but as a transformative figure within the corporate ecosystem.

The insights gained underscored the facilitator's pivotal role in steering multidisciplinary groups toward a design-led process. This role echoed the broader responsibility of a CDO in bridging, balancing, and giving voice to diverse perspectives — be it business goals, users' needs, or team decisions. The facilitator's influence in instilling empathy, fostering holistic perspectives, and guiding mindset shifts mirrored the challenges faced by a CDO in harmonizing diverse thoughts into a coherent design narrative. The well-organized workshop ecosystem, essential for dynamic ideation, mirrored the need for structured leadership within organizations.

The workshop illuminated the imperative of implementing more empathic, holistic, and decision-making methodologies into the innovation process. Design thinking principles served not just as tools but as transformative agents. The Six Thinking Hats methodology showcased its applicability in design strategy, aligning seamlessly with the demands of managing design processes and teams. This emphasis on structured problem-solving methodologies validated the hypothesis that design-led approaches equip companies to respond effectively to evolving market trends, emerging technologies, and shifting consumer expectations.

The user-centric approach, cultivated through immersive activities and empathic exercises, became the bedrock for ideation. This aligned with the hypothesis that placing the user experience at the heart of innovation fosters brand loyalty and fuels innovation rooted in real-world needs. Furthermore, the workshop showcased that design, when integrated into corporate culture, propels a transformative shift toward collaboration and creative problem-solving.

In summary, Workshop 2.0's insights serve as a blueprint for future Co-design Sessions, transcending the boundaries of technical proficiency. The dynamic interplay of design leadership and facilitation emerges as a guiding light for the CDO's strategic role. The emphasis on empathy, holistic methodologies, and a user-centric approach resonates with the broader goals of the Co-design Sessions — building design-oriented innovation processes, fostering a design culture, and developing concepts positioning Revigrés as a market leader. These insights serve not only as markers for the journey but as transformative elements shaping a design narrative that extends beyond individual workshops, steering Revigrés into a future of innovation and design excellence.

About the Authors:

Gisela Pinheiro, a product designer and doctoral student, focuses her research on the Chief Design Officer's role in driving radical innovation at Revigrés. With 6 years in lighting design and a master's, her expertise merges design methodologies with management for business impact.

Teresa Franqueira is an Associate Professor at the University of Aveiro, is a designer and has a PhD degree at Politecnico di Milano. She is the International Coordinator of DESIS Network and Sustainability and Member of the Executive Board of Cumulus Association.

Acknowledgements: we extend sincere gratitude *Fundação para a Ciência e a Tecnologia* (FTC) for funding our research activities. Our appreciation also goes to Revigrés for their invaluable support and collaboration, as well as the dedicated workshop participants for their unwavering commitment to learning. Special appreciation to Revigrés' top management for their encouragement and guidance throughout this journey.

This work is financed by national funds through FCT - Fundação para a Ciência e a Tecnologia, I.P., under the project UIDB/04057/2020.

KICKSTARTING CULTURAL ENTREPRENEURSHIP VIA CROWDFUNDING. DISRUPTING FROM BOTTOM UP.

Nora Szeles*[a]

DOI: 10.63442/PXFW1708

KEYWORDS | ECOSYSTEM, CROWDFUNDING, DEMOCRATISING ACCESS TO CAPITAL, INNOVATION, SOCIAL CAPITAL, SUPERDISCIPLINE

ABSTRACT | Crowdfunding is most probably the best go-to-market strategy for the entrepreneurs or creators in the cultural and creative industries (CCIs), as it unfolds, leverages and innovates the network effect easily by unlocking fan-, trust-, and social capital to establish the new brand. As often emphasized, it democratizes access to resources, innovates processes, reinvents, and pivots business models. The somewhat unusual "Prologue" is motivated by personal experiences, but it extracts 25+ years across capital markets and findings from academia and industry. Illustrating Hungarian and international cases, this study adds further depth to the phenomenon of how creative power that implies innovation and spillovers can unlock economic growth by measurably building an interconnected ecosystem for small- and medium-sized enterprises (SMEs) to overtake shortcomings of monetary policy. This study is built on three propositions: on the micro level, it presents crowdfunding as a simple, innovative service pivotal for validating, fundraising, marketing, and community building for creators, on the meso level, as a marketplace or project webshop, on a macro level, the uprise of ecosystems versus economies. Considering recent regulations that render crowdfunded equity a secure, cross-border, disintermediated investment asset class, this study adds further to how crowdfunding can function for CCI entrepreneurs, ecosystem participants, and policymakers.

1. The king is naked. Prologue

On June 21, 1990, as a first-year student hostess, I witnessed the reopening of the first stock exchange of the communist block after its 42 years of imprisonment. The five-day-long mesmerizing ceremony of the Budapest Stock Exchange (BSE), from now on referred to as the Ceremony, paid tribute to the regime change. The launch of the trading of one single share, IBUSZ, which would hardly reach the headlines today, captivated a global audience. This momentum, combined with the incomparably rich bourse history of 85 years under the Monarchy (1864-1948) –50 years during which the Budapest Commodity and Stock Exchange's yields outperformed (!) that of London and New York (Radnai & Szatmári, 2024; Korányi, 2014) – should have secured an everlasting competitive advantage.

But Hungary did not succeed in winning the game. Despite echoing the 'We are the first' slogan for decades, it de facto lost all its competitive advantage within a few years (Reininger & Walko 2020; Szeles, 2000).

What went wrong?

This question has been the central focus of my research in the past twenty years, but since I have been deep diving into the startup subculture, newer and newer layers seem to be unfolding. Still researching the answer since, even after my first books on the history of the stock exchange (Szeles, 2004; 2015), an opaque factor seems to be crystallizing that *one of the fatal reasons for this failure is negligence of the unsupported innovation ecosystem that led to the underperformance the pre-IPO pipeline*.

During the 34 years since the Ceremony, the lack of innovative, long-term-minded governmental policy (except for a few periodic or sporadic top-down economic policy successes) has led to a definite economic lag (Jaksity et al., 2023; AFME, 2023; Balogh & Langmar 2024). Stuck in the middle-income trap (Karsai, 2022) rounds up the drama of this small, export-oriented, traditional (aka non-digital) economy with its systematic global exposure[1]. This period of economic transition attracted significant academic attention (Reininger & Walko, 2020; Lucey & Voronkova, 2006) that detected underlying factors that hindered competitiveness. Thus, the rise of successful ventures and sociological patterns like paternalism (Kornai, 1995) have also been studied that withheld the accumulation of social capital that could enable and even finance organic, bottom-up initiatives ecosystems to outperform the old economy.

Now, it’s time to disrupt this legacy digitally.

2. Introduction

Inspired by the central themes of the Cumulus conference, first of all by “bridging design and economics” but including "centers and peripheries,” “converging bodies of knowledge," "systemic complexities," and "challenging societal structures," I attempt to present how crowdfunding resonates with these concepts. Considering the concise format of the conference paper, and as a professional in capital markets and crowdfunding, I have opted to present a pragmatic approach grounded in empirical experience.
One major impact of internet-based digitalization is that, on a gross scale and at an accelerating rate, it ensures increasingly easier access to information and services for mankind. This progress leads to the mass decentralization of services, which have been overwhelmingly dominated by intermediaries.
Disintermediation poses a significant competitive challenge for traditional institutions, such as banks: non-institutional, competitive service providers threaten their century-old market positions (Parker et al., 2016).

[1] The scope of this paper precludes a detailed inclusion of Wallerstein's world-systems theory, a notable concept in mainstream social science. However, it is pertinent to briefly mention the semi-periphery phenomenon within the centre-periphery model (Wallerstein, 1974). This model articulates the division of labor and resource exchange between core and peripheral nations, underscoring how 'emerging' semi-peripheral economies continually evolve. This paper aims to contribute to the hypothesis that if ecosystems can supersede economies, it might alter this semi-peripheral dynamic as well.

This change opens up new opportunities in design, particularly in interaction design, as it is a crucial element in the user journey and a key aspect of digital competitiveness. Digital growth and scalability largely depend on software, while user acquisition ultimately hinges on the user experience, which is shaped by design (Norman, 2014). This relationship creates a spillover effect that influences digital competitiveness and entrepreneurship, leading to the emergence of novel "alternative economic frameworks" such as the "sharing economy" and "peer-to-peer networks," which can be viewed as ecosystems. In contrast to an economy, which is organized and institutionalized from the top down, an ecosystem employs a bottom-up approach, characterized by having interconnectedness and "fluid borders" – as opposed to being institutionalized or regulated (Tiwana, 2013). This concept paper argues that crowdfunding, as a digital fundraising tool, has the natural capacity to connect, catalyze, and bridge the previously mentioned domains by disintermediation and reconnection and fuel interconnectedness, the major characteristics of an ecosystem.

I believe that contrary to the misconception that crowdfunding is merely a fallback option for cultural entrepreneurs who have failed to secure an industry leader's support, it should be recognized as a first choice. This paper shall introduce crowdfunding's unrecognized potential as an ecosystem driver.

As described by the entire mainstream literature, crowdfunding democratizes access to resources for creators on a mass scale, such as information, services, communication, marketing, and capital. It empowers creators to connect to their target audiences, yet in the critical early phase of a venture called Death Valley (see Figure 3), it ensures abundant independence and enables self-sustainable, innovative, efficient strategies, which in a critical mass can empower the cultural entrepreneurs to breakthrough and leverage their effect on micro-, meso- and macroeconomic competitiveness. This has been recognized. However, as a renewed approach, this article argues that crowdfunding is not only a tool but a driver that liberates creators from the constraints of a conservative industry structure. As ecosystems are to be fueled with capital, ultimately, crowdfunding is an organic ecosystem builder. This third type of ecosystem driver can change the traditional CCI ecosystem landscape that is yet dominated by i) a monopoly (state) or ii) monopolistic (dominant market player)-driven ecosystems. Crowdfunding is the most organic or bottom-up driver and, therefore, the most sustainable. This proposition, which I actively advocate in my role as a capital market professional, will hereafter be referred to as the 1st proposition.

If policymakers recognized crowdfunding as a vital cog in innovation, if they could support, accommodate, and take advantage of it, then they could speed up the dynamics of creative and innovative production at lower costs. If incumbent capital market service providers, including stock market operators and institutional investors, recognized and supported this renewed approach as an innovation funnel, that could lead to more IPO-ready ventures, whose founders as alumni startup founders would be best recognized upon their reinvestments into early phase ventures. Taking this alumni factor into account, in concluding with Figure 7, I will summarize by presenting how to develop the famous bell curve (World Bank, 2013) into a circle.

Within the framework of the track Bridging Design and Economics and the format limits, I consciously simplify the model to focus on the primary purpose of this paper, which is to demonstrate the power of crowdfunding as a relatively new tool rather than the products funded through crowdfunding or borderline financial products such as NFTs. As the cited literature elaborates on many aspects of economic history to contextualize the Prologue and extensively on crowdfunding, I narrow the scope to focus on demonstrating the potential of crowdfunding as an instrumental and creative tool for CCI entrepreneurs in their go-to-market strategies. Additionally, I aim to show how ecosystems with high interconnectedness and "fluid borders"—though less visible—could function more effectively than traditional institutional economics. As always, I cannot resist including some healthy sarcasm or humor. As a startup founder myself, who takes risks on my account to kick bricks off walls to make things happen, I mean it well.

3. Reframing core paradigms: innovation = ecosystem + investments

The United Nations Conference on Trade and Development (UNCTAD) defines the creative economy as "activities centered on fostering development by combining cultural, social, and tourism goals with the application of technology and the exploitation of intellectual property" (UNCTAD, 2022). To add more dynamics and to distill this approach further, in this paper, we would call these "activities" power and regard **creative power as an innovative, aesthetical, efficient, diffusive, spillover-generating, sustainable progress**. (As a distinction from art, which can be described as more self-oriented). This long-term progress can be efficiently financed by short-term crowdfunding campaigns. This study aims to capture the essence of this phenomenon rather than delving into the extensively discussed factors of campaign success.

In this short paper, the following factors of CCIs are considered:

- **The value added** of CCIs represents approximately 3.95% of EU value added and employs around 8 million people, including around 1.2 million firms, over 99.9% of which are small and medium-sized enterprises (SMEs) (EU, 2024). Besides this ratio, CCI, taking advantage of its social dimension, plays a great part in driving innovation and creativity across other industries. This cultural impact element or power is measurable. The Creative Economy Outlook 2022 report by UNCTAD highlights that the creative economy is one of the world's fastest-growing sectors, creating employment and income, promoting innovation, and contributing to societies' well-being;
- **the resilience** of the creative economy also translates to economic security in the form of **soft power**. The UNCTAD report also notes that creative industries were more resilient during the COVID-19 pandemic than other service sectors, with creative services exports only falling by 1.8% in 2020 compared to a 20% fall in exports of all services. For example, the French creative economy includes over 300,000 businesses and generates twice the revenue of the automotive industry (Runde et al., 2020). The pandemic had a significant negative impact on these industries, with substantial job losses and revenue declines. Governments, in response, initiated recovery plans and provided support to stimulate the revival of the cultural and creative sectors. The United Nations designated 2021 as the International Year of the Creative Economy for Sustainable Development, emphasizing the role of creative industries in enabling global economic growth and social and cultural development. This recognition extends to G20 leaders who have identified culture and creative industries as drivers for sustainable development and economic resilience (UNCTAD, 2021);
- **the innovative impact of CCIs** on the growth of other sectors and innovation is a measurable effect. CCIs stimulate business, technology, and society, driving innovations and knowledge transfer (Klein & Spychalska-Wojtkiewicz, 2020). Although most CCI projects are not innovations as determined by the Oslo Manual (OECD 2018), CCIs play a strategic role in bridging art, business, and technology, thus affecting external industries. The creative sector is defined by its dynamic nature and its focus on producing original or unique goods, often organized online. Design-based innovation creates new markets and facilitates the adoption of new meanings, highlighting the sector's potential to address further societal challenges like climate change and demographic shifts. As a solution to the traditional center-periphery problem that describes the gap as a social product between regions, today, digitalization and communication can help solve and enhance the growth of social capital and participation (Horányi, 2006).

Rykkja elaborates on the broad and complex concept of creative and cultural innovation as follows (Rykkja 2023, p.2).

„A rationale for studying the use of crowdfunding within the creative economy is that the CCI drives innovation and generates spillovers across the wider economy (Cunningham & Potts 2015; Potts & Cunningham 2008). It has been argued in the management literature that studying managerial innovation and experimentation in the creative economy (Bonet & González-Piñero 2021; Lampel & Germain 2016) may provide templates for the coordination of economic activity in other sectors (Bakhshi & McVittie 2009; Boix-Domènech & Rausell-Köster 2018). Crowdfunding adoption in the CCI is one such example because it was within the CCI that crowdfunding as a practice first emerged (Agrawal et al., 2013; Dalla Chiesa & Handke, 2020). This process of diffusion from the CCI towards the wider economy is also acknowledged in the general literature on crowdfunding. Contributions highlight the usefulness of empirical findings of 'early-stage creative projects' (Agrawal et al. 2015) for a better understanding of the adoption and use of crowdfunding in '… other, non-artistic projects and business ventures' (Macht & Weatherston 2015, p. 193). In other words, there is a vetted tradition for utilising findings from studies that use the CCI as an empirical context for understanding the adoption and development of crowdfunding as a business model in general."

- **Alumni culture is key:** Provided that the ecosystem develops and nourishes an alumni culture where successful entrepreneurs give back to prospective entrepreneurs and newcomers can access the experiences of alumni (for example, through mentorship), then sustainability is ensured. In Chapter 3, the "startup mafia model" is introduced. Notably, but not detailed further herein, education and communication are the pillars of its sustainability. This key concept is visualized in **Figure 7**.

And here comes the 2nd proposition, or the vision of the concept: by viewing digital economic ecosystems as informal yet transparent networks with low barriers to entry but with high added value through inclusive and efficient participation and innovative culture, ecosystems can transcend traditional economies based on regionalism, traditional culture, and physical resources, generating sustainable growth to bridge the gap between centers and peripheries, or between inefficient economies.

The real question is how to make it work. The 2nd proposition suggests that venture capital shall fuel the ecosystem to produce innovative products and services and argues that crowdfunding is the most accessible and, therefore, the most efficient and resilient form of capital "to do the job" (Christensen, 2015). Being a relatively new digital tool, it will not instantly create impact, but in the long term, it can certainly reach the critical, resilient mass from the bottom up. First, a short overview is presented about the venture capital industry.

4. Innovation as a function of venture capital investments: a short overview of the institutional, the private and the crowd capitalists

Innovative and creative ventures, often lacking collateral for traditional bank loans, have historically relied on alternative funding sources if bootstrapping or using personal capital and revenues does not suffice for competitive growth. This is where institutional venture capital comes into play, offering capital in exchange for equity. The concept of venture capital has been around since the Renaissance (Gompers, 1994), but its prominence surged with the advent of the Internet. This technological revolution particularly benefited businesses focused on technology or software (e.g., Software-as-a-Service, SaaS) by enabling them to scale rapidly while reducing unit costs. For the sake of growth, startups sacrifice profitability in their early years, and robust growth must be financed with external capital (Karsai, 2020). The relevance of venture capital in this context is not just to illustrate how thousands of companies, including CCIs, have utilized venture capital for growth: "Without significant venture capital investments in the risky early stages of a project's lifecycle, innovation in the economy would be stifled" (Khan et al., 2021). The rule is very simple: if there are no risk-takers, then there is no innovation. Banks aren't risk-takers. The state, on a mass and democratic scale, only temporarily takes risks. Thus, the accessibility to venture capital is crucial.

For a standalone but comprehensive conclusion, the following section will shortly summarize the well-known advantages and disadvantages of each financial service in the context of the discussion.

4.1 Non-institutional investors: clubs and mafias

The distinction between institutional and non-institutional investors is not based on whether they are incorporated but rather on whether they manage their assets or those of clients. The latter is always regulated. Non-institutional venture capital is available from business angels and family offices that decide over their own money, most usually within their business domains, building up portfolios with smaller ticket sizes and actively mentoring the investees.

- **Business angels** are usually solo entrepreneurs who earn their wealth from exiting successfully from former companies. Their cheque is much lower than that of the VCs but referred to as smart money: their mentorship is usually worth as much as the money that they offer. Angels voluntarily join semi-public clubs, known as BAN's (business angel networks), that collect and curate inbound funding requests in the form of pitches and where they can syndicate investments with fellow angels.
- **Family offices** are incorporated private wealth management companies that manage single or multiple portfolios as a cross-generational heritage and often use a fraction of their wealth to start investments. Their visibility is even less, and accessibility is even harder than that of the VCs: if they handle only their private capital, then they do not fall under regulation.
- So-called **Startup Mafias** (Deep Ecosystem, 2022) are excellent examples of alumni-based ecosystems. Undoubtedly, the most known example of that is the outlier success of Skype in 2011, when – 20 years after the Ceremony – it was bought up by Microsoft (earlier by eBay), making the six founders, including Estonian developers, billionaires, and they all reinvested a large part of this capital in local startups. The world learned that Estonia is a country. Seeding this fertile ground, Estonia today – despite, or independently from, its little physical size and without almost any tradition in capital markets – is per capita and GDP one of the leading digital economies, marked by the largest number of unicorns[2]. These types of ecosystems also rely on fandom and need, using tools of communication, leadership, marketing, and branding. Another good example is the Paypal story. But even the birthplace of Paypal, Silicon Valley's flourishing started with Hewlett and Packard's legacy. Spotify and Pixar built up an ecosystem as well.

Twenty years after the Ceremony, a former communist Baltic culture succeeded in accommodating the ecosystem concept of the 1st proposition. Well, daring to oversimplify the question, why couldn't IBUSZ, or the first Hungarian tech prospect unicorns, LogMeIn, and Prezi[3] catalyze the growth?

4.2 Institutional investors: rare venture capital in CCI

Venture capital investment in the CCI is a challenging issue. CCI entrepreneurs often struggle to attract venture capital due to factors like a lack of investible and scalable business models, limited tangible assets, and difficulties in assessing and protecting intellectual property. Monopol or monopolistic ecosystems dominate most segments of the industry. Foundations, grants, collectors, philanthropists, and crowdfunding are available for the arts. Industrial design in branded serial production, e.g., fashion and luxury goods, lifestyle companies have better access to venture capital as

[2] See the full list: https://investinestonia.com/the-full-list-of-estonian-unicorns/
[3] LogMeIn and Prezi are very successful, now US-based, Budapest-born tech companies.

- Computer-aided design (CAD) and streaming-based music platforms are investable: among the 1000+ startups that are priced above a billion USD[4], aka unicorns, among the strongest brands, there are a few from the CCIs: Canva, Design, PicArt, and Pixar. (Spotify is often referred to, but shall not counted herein; that is a tech company.)
- Extra profit from love brands and celebrity brands is also appreciated by venture capitalists. Mejuri, a direct-to-consumer jewelry company, secured $28 million. Depop, a platform for fashion items, received $105.6 million. Skims, founded by Jens Grede and Kim Kardashian, raised $399 million. Allbirds, a sustainable shoe brand, secured $202.5 million in several rounds.

1. **Non-transparent and not accountable decision-making**: just as in the case of each institutional investor, VC's investment policy is regulated therefore, it easily excludes targets due to strategic reasons, but that can be better forecasted based on their public profiles than their opaque decision-making processes that makes it inefficient for project owners to count on VC funding. For example, the now-billionaire CEO of Canva, Melanie Perkins, was turned down over 100 times by VCs.

2. **Geographic gaps:** Venture capitalists typically invest in nearby companies, leading startups to gravitate toward investors. This pattern affects the global distribution of VCs, creating distinct regional disparities, as shown in Figure 1. This distribution perpetuates a divide between central and peripheral areas. Post-1990, Central and Eastern Europe, previously viewed as a homogeneous region, no longer fits this description due to new digital divides. Countries benefiting from "digital territorial expansion" and the influence of alumni ecosystems and growth-focused VCs are on the successful side of this divide.

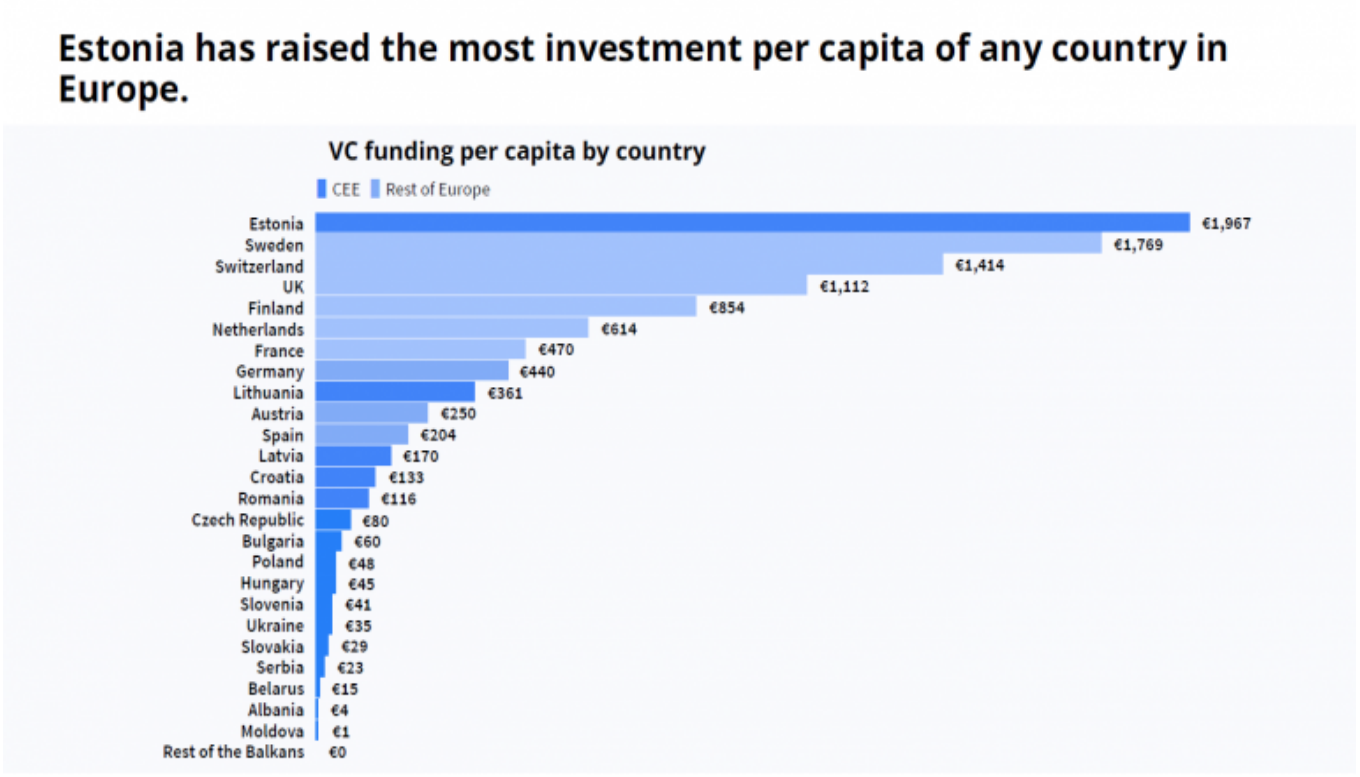

Figure 1: Venture funding per capita by country until 2021 Source: Dealroom.

[4] See the full list here: https://www.cbinsights.com/research-unicorn-companies

3. **Cyclicity:** the significant risk of institutional investors, such as those from venture capital firms, lies within their cyclical nature. Their investment activity, just exactly like bank loans, can be dramatically affected by economic cycles. In an economic downturn, deal flows can halt abruptly. In times of crisis, they generally prefer holding cash and sustaining their existing portfolio by follow-on or bridge finance. This is what exactly happened in the 2008 financial crisis, exemplified on September 15, 2008,[5]., which took the US Congress under pressure to invent a tool to stimulate the economy and halt the downturn (Szeles, 2022).
4. **Regulation**: Realizing the rise of the internet and motivated by the early successes of digital crowdfunding marketplaces such as Artistshare and Kickstarter, or – today's largest reward-based crowdfunding platform of creators[6] –, in 2012, Congress passed a landmark regulation, the JOBS Act, that legitimized investment crowdfunding, a potential natural choice for even a CCI entrepreneur in a more mature phase – perhaps, after having completed a reward-based crowdfunding campaign.

4.3 Let's go crowd: platform-based communities and platform economics.

The Regulation Crowdfunding provision within the Jumpstart Our Business Startups (JOBS) Act – deliberately named to emphasize its goal of job creation – eased the requirements for costly prospectus authorization within specified limits. Among the first equity crowdfunding platforms established in response to this change was Wefunder, founded "to address the funding gap left by institutional investors' rejections" – as referred thereto earlier. Since then, Wefunder, along with other equity U.S. platforms, has collectively raised over $ 700 million from more than 3 million individuals (Wefunder, 2023).

The European Crowdfunding Service Providers Regulation (ECSPR) came into effect in 2022. Since November 10, 2023, only licensed platforms are permitted to offer investment-based crowdfunding. Reward-based and donation-based crowdfunding remains unregulated, as these fundraising methods do not involve regulatory risk and information asymmetry, those factors that necessitate regulated investor protection. With the JOBS Act and ECSPR, the last regulated physical investment asset class is born, that of the pre-IPO companies, but crypto assets are also being regulated (Tokeportal.com, 2023). With the introduction of new regulations, for the first time in history, so-called non-sophisticated or everyday investors are safeguarded when investing in startups or early-phase companies. For creators who plan to develop alongside the alternative finance lifecycle, as exhibited in **Figure 3**, these regulations not only enhance safety and transparency in planning the financial strategy but reduce costs and risks in cross-border strategies and allow crowdfunding up to € 5M per year without further, costly legal arrangements. This ticket size is very much competitive with any other form of institutional capital, not to speak of the secondary market service that enhances the liquidity of the crowdfunded securities, thus reducing investors' risks. (Without stressing too much vision into this short paper, blockchain-based tech trends like tokenization will most probably soon compete even with traditional IPO markets such as stock exchanges.)

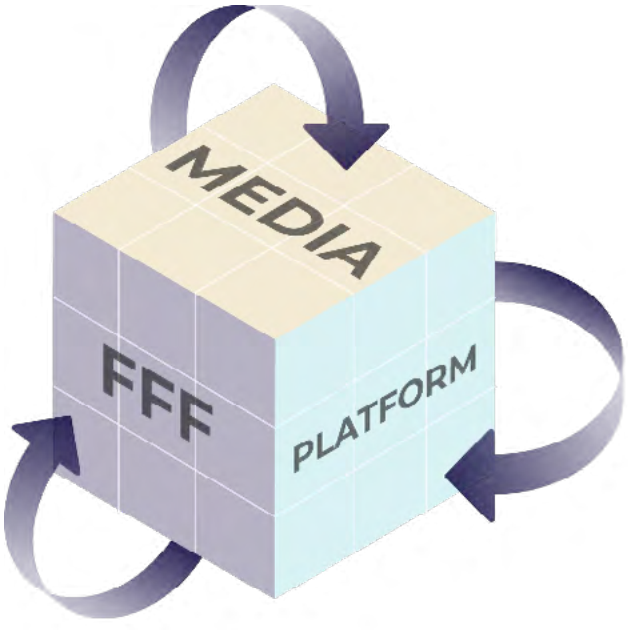
[5] The collapse of Lehman Brothers led to widespread panic in the financial markets, significantly impacting the availability of venture capital as well: many VC firms faced reduced funding from Limited Partners (LPs), which drastically limited their ability to support SMEs and startups. This situation was exacerbated by the near freeze of the entire banking system, leaving the economy in a dire state without finance. The aftermath saw a surge in bankruptcies and unemployment reaching unprecedented levels. It took global economies more than five years just to stabilize from this shock. Venture capital funding, according to data from the National Venture Capital Association, dropped from $28.3 billion in 2008 to $17.7 billion in 2009. Unemployment rate more than doubled, peaking above 10% in late 2009, reaching a high not seen in over 20 years. Early-stage companies and SMEs were cut off from traditional bank financing. High costs of public offering of shares, including the need for an authorized prospectus disabled them to sell shares. The JOBS Act made a significant mark in financial history by enabling early-stage companies to be investable by the public, effectively regulating, thus creating the last segment of physical asset classes (Epstein 2016).

[6] To clarify, while Kickstarter remains unregulated, it, along with other existing platforms at the time, demonstrated the online platform-based mechanism of directly connecting creators with clients.

So, what is crowdfunding exactly? In itself, it is as old as mankind: an open call for friends, family, and unknown prospective investors/donors to finance something. People with an idea but without money always went around the corner to ask for money. Mozart sought funding for three piano concertos by proposing a subscription model to potential investors. The Liberty statue was financed by newspaper advertisements. But that was local. With the rise of the internet, crowdfunding experienced a digital reincarnation, expanding its reach on a global scale. The key to success in these projects lies in **their internet-based, computer-mediated, asynchronous communication campaigns (**Dematos & Maehle, 2023), **with the addition of efficient targeting of the audience in social media.** This mechanism has now become a prominent subject in communication theory research. In this paper, we add further developments as also observed in a survey (Szeles, 2023): the more synchronized the communication between the campaign owner and the potential supporters or investors is on the campaign page, social media, or at online/offline events, the greater the backers' or investors' engagement, and their sense of reaching agreement, which can be called participation (Horányi, 2006). **Successful campaigns are those that have reached an agreement with their audience, an investment agreement**. This is the conversion mechanism of crowdfunding.

While social capital is a macro-level approach, on the meso-and micro level, network capital, including friends, family, fans (or fools, often added sarcastically, but it stands for followers in social media (FFF) is the cornerstone from where a project or startup can kickstart its go-to-market strategy. Using crowdfunding not only as a periodic tool but as a business model (Rykkja, 2023) by converting FFF — also referred to as fan-capital, Direct-to-fans (D2F) (Tosatto et al., 2022), or affective marketing (Hills 2015) — into users and donators/backers/investors; and by uniting audiences with the platform audience, crowdfunders can build a strong brand, a legacy- or a love brand. And as Figure 2 demonstrates, this can spill over into the wider economy.

"Bűvös Kocka [7]of Crowdfunding"



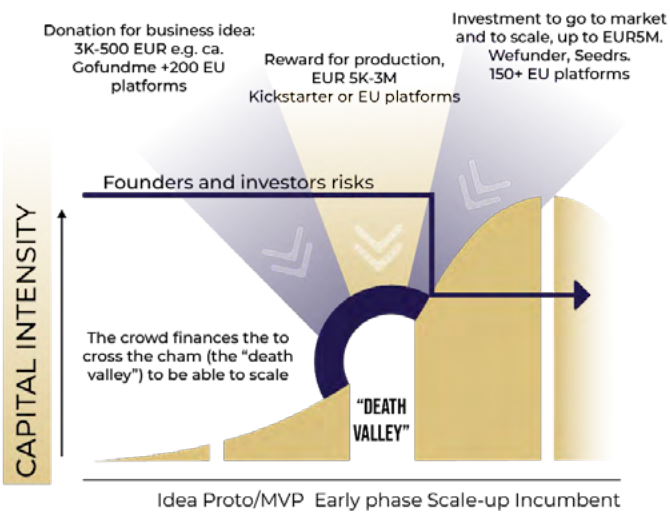


Figure 2: The inception points of the spillover effect of innovation.

[7] The Rubic Cube or Magic Cube is a Hungarian invention (1974)-is applied here just to visualize how to make sense of crowdfunding-as-communication, as a mathematical model.

The magic lies within the sustainable conversion mechanism of crowdfunding: on the meso-and micro level, network capital —including FFF, is the cornerstone from where a project or startup can kickstart its go-to-market strategy. By momentum-building communication strategy, further and further layers can be reached, new audiences can be added, and the wisdom of the crowd can be insourced (World Bank 2013). The original, creative, innovative project idea can, through crowdfunding, diffuse and create spillovers in the wider economy.

Paschen (Paschen, 2016) conceptualized the 2nd proposition eight years ago that the four types of crowdfunding can fill the gap in traditional financial services such as bank loans. Since then, evidence of platform performance and regulation has solidified the concept that I exhibit in Figure 3. Further highlights of the World Bank study (World Bank 2013) and findings from recent studies are added.

Table 1. How crowdfunding covers the financing needs of startups and SMEs. Inspired by the chart of the World Bank (World Bank), 2013.

Figure 3. **2nd Proposition: Crowdfunding can completely replace the traditional financial services throughout the company life cycle**	**Types of crowdfunding for a cultural entrepreneur (not exclusively for b2b)**
	Donation campaigns: creators ask for donation without offering rewards. Mostly used by nonprofits. Platforms like GoFundMe support business ideas, raising thousands of euros for projects that resonates with emotional, philanthropic and impact / difference making motivations of the donors. The stronger the social media presence, the higher the chances are – all through the crowdfunding journey. Reward campaigns collect donations of backers in exchange for piloting/prototyping/launch pre-sales via rewards for future products. Counts as post-market validation. Platforms like Kickstarter, Indiegogo can multiple and engage fans and unlock fan capital and convert it to cash, build fame and even a love brand. Investment campaigns: after succeeding reward-based sales, creators as ventures with investible business plans can get accepted by licensed platforms to launch equity campaigns that unite fans, clients, FFF's and investors as early-phase, high risk companies offer high potential returns. This is the multiple conversion effect. More mature, creditable ventures can launch debt campaigns. Purposely, only the growth curve is shown of the bell curve that is covered by crowdfunding. However, investment crowdfunding can also be interesting for mature companies, and with the planned upgrade to the €8 million limit, and with the secondary trading function, the platform can practically function as a stock exchange.

There are two further key takeaways from Figure 2:

- The World Bank proposed that crowdfunding is a key tool for early-phase companies to bridge the "Death Valley" — the critical phase where they run out of capital and are not yet attractive to institutional investors or banks (World Bank 2013). But the crowd can be a source of capital for them. Therefore, crowdfunding can attract dormant capital into the economy and also serve as a mechanism for crowd diligence, where potential backers collectively assess and comment on the legitimacy of a campaign: if any fraudulent or contradictory information is detected, interest in the campaign can rapidly decline, leaving the untrustworthy founder without support. This crowd-based vetting process, called crowd diligence, is essential in mitigating fraud in crowdfunding platforms.
- The curve exhibits another famous concept, that of the “crossing the chasm,” which can be regarded as the Death Valley of growth (Moore 2014). The concept proves that in the above-pictured interdependency with novelty adoption by customers—which begins with early adopters and continues with early majority, late majority, and laggards—the critical chasm lies between the early adopters and the early majority. Most early-phase companies fail with their go-to-market strategy or product-market fit at a mass scale. To conquer this risk, crowdfunding can help innovators validate their concepts with a large amount of feedback during a reward campaign and get better prepared for crossing the chasm.

To conclude, the 2nd proposition to reflect the CCI entrepreneur, major, research, and evident-based advantages follow, related to platform economics.

- Reward- and donation-based crowdfunding practices are most used within the culture sector (Shenor et al. 2020; Rykkja 2023). More and more cultural entrepreneurs utilize this experience in upgrading their crowdfunding experience and launching equity campaigns successfully. Reddit is a famous example.
- Crowdfunding is a process by which new value is added to the process of production, distribution, and creation of exchange and use value) constitute innovation. According to standard OECD/Eurostat definitions and measurement procedures, the use of crowdfunding may create and lead to the diffusion of another potential innovation (Banet-Weiser & Castells 2017).
- Entrepreneurs’ dream across sectors is to build a love brand. Due to their fan base, love brands are the most resilient and independent from market shocks due to their domesticated resources. Crowdfunding is the tool to maximize fan capital for financing as it allows a fan to renew their connection to the brand and be part of its journey (Scott 2015). Fashion brands, and for example, new food (e.g., craft beer like Brewdog, lots of beverages, vegan food brands), new industries such as fintech, and impact-driven sustainability projects maximized crowdfunding for this purpose.
- Crowdfunding platforms operate in a webshop model. As online marketplaces, they need to develop both sides of the market and match supply with demand. For campaign owners using crowdfunding as a business model, not merely out of necessity, it's crucial to apply e-commerce-like marketing and communication strategies. Campaign owners need to utilize network effects through effective marketing (Hills 2015), framing (Moradi & Dass 2019; Entmann 1993), and Direct-to-Fan (D2F) mechanisms to foster engagement effectively (Tosatto et al. 2022). The widely applied and researched online marketing strategy includes leveraging social media to build the campaign momentum. Achieving near-synchronous communication, aka participation, is key to creating this momentum. This is the **3rd proposition** that adds further depth to the well-established herding effect that is the other key driver of momentum building (Agrawal et al. 2015; Petit & Wirtz 2021).

- For platform operators or crowdfunding service providers, entry barriers are significant. Typically, these platforms adopt a success-fee-based B2B model and earn 5%-15% of the capital collected, which entails risks, given the success rate is 40%-80% of the campaigns launched. Their revenue increases with the quantity of capital, therefore, with the quality of campaigns they attract, and top campaign creators often favor platforms with larger user bases. Liquidity attracts liquidity, as in all segments of capital markets. This is how Kickstarter corned out the market (Rykkja 2023). While this study does not delve into detailed platform economics, considering the industry's current state and its oligopolistic market structure, this business model in a relatively new market—where intensive education is necessary to evangelize prospective clients across diverse financial cultures—demands substantial capital expenditure (CAPEX). For investment-based platforms, achieving ECSPR license readiness incurs additional costs of €100-150k, besides expenses on application development, marketing, staffing, and legal costs, including user verification tools (Know Your Customer, KYC) and anti-money laundering (AML) measures.

5. Meanwhile in Hungary

Thirty-four years after the Ceremony, one year after the BSE's IPO, the Hungarian economy is now in the latest laggard phase as measured by decisive mainstream capital market-related economic factors, as published by the National Bank of Hungary and AFME as well (MNB 2022; AFME 2023). Within this study, only a few of these are presented, embedding them into a well-elaborated phenomenon and concluding with the current status of venture capital and crowdfunding[8].

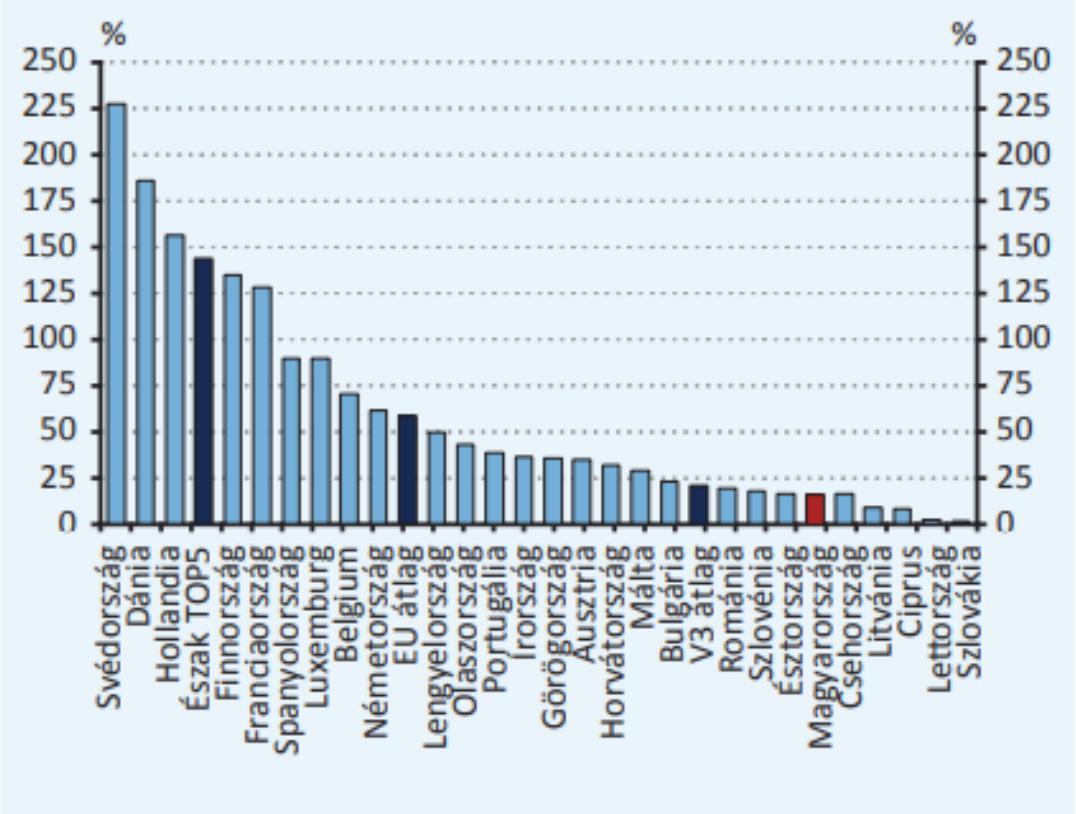

Figure 4: Stock market capitalization in comparison to GDP in 2021

[8] This late laggard phase is also explained by the BSE's lack of strategy to integrate into the European capital markets in that regulation-driven consolidation (Szeles & Marosi 2000; Szeles et al. 2001). The impact of the missed opportunities is another important factor but would not fit within the scope of this paper.

> “In Hungary, stock market capitalization as a percentage of GDP is low in international comparison, at 16.5%. This places Hungary behind Poland in the regional context, but ahead of the Czech Republic and Slovakia. In Western European and Scandinavian countries, market capitalization often exceeds 100%. A diversified financial system underpins competitive economies and sustainable growth. In contrast, financing in Hungary primarily occurs through banking channels, creating significant vulnerabilities, especially during credit crises, as it complicates access to resources for companies. Achieving a 30% capitalization ratio could potentially increase the economy's potential output level by 0.2-0.3 percentage points.”
> (Source: MNB, 2022)

The transformation following the Hungarian regime change led to significant societal and economic shifts. Research indicates an increase in risk averseness among the population, a trend often attributed to the uncertainties of the post-regime economy, resulting in a decline in social capital. Traditional networks were disrupted, and new forms of social organization were slow to develop (Sik, 1994). Moreover, the transition period reinforced top-down cultural norms, reflecting a continuity of paternalistic attitudes from the previous regime, which hindered the development of more participatory and democratic organizational cultures (Kornai, 1995). This paternalism, deeply ingrained in the societal fabric, continued to influence both public and private sector dynamics, impacting decision-making processes and leadership styles (Karsai 2020).

According to Dealroom's research (Balogh & Langmar, 2024), Hungary's peak in the stock market was in 2020, supported by European S3 funds and incubators. In 2020, the investment ratio was 45 euros per capita. This figure was five times higher in Austria, ten times in Germany, and 43 times in Estonia. Research also shows a growing reliance of the region on state or EU funds for venture capital, increasing from 25% to 40% from 2016 to 2020 while remaining stable at about 6% in Europe. This suggests these countries are gaining more influence in state funds, unlike Western countries where risk capital is privately funded to the market. The limited availability of venture capital particularly affects the growth of high-potential, young, innovative companies (Karsai, 2020): 31% of startups valued over one billion dollars did not or could not use venture capital, compared to only 7% in the whole of Europe. In the CEE, five countries received 82% of the total investment value: Estonia, Czech Republic, Poland, Hungary, and Romania. Currently, Hungary lags far behind Estonia in terms of startup investments relative to GDP per capita: whereas in Estonia, GDP is €27k / capita and investments are €2k/capita, in Hungary, GDP is €18k/ capita, and investments are as low as €7/capita.

So where is the money? As highlighted by the World Bank, crowdfunding is a tool to unlock dormant (uninvested) capital and make it work. (World Bank 2013). Dormant capital mirrors distrust in the state (which is not contradictory with paternalism) and lack of investment possibilities and preserves the gap. Hungary is recorded in this negative trend: Figure 5. shows that "in the European Union, only Greece, Latvia, Lithuania, Portugal, and Slovakia had a higher GDP ratio of cash in circulation. In the CEE region, only the Slovak value exceeded the Hungarian." (Hungarian Banking Association, 2019).

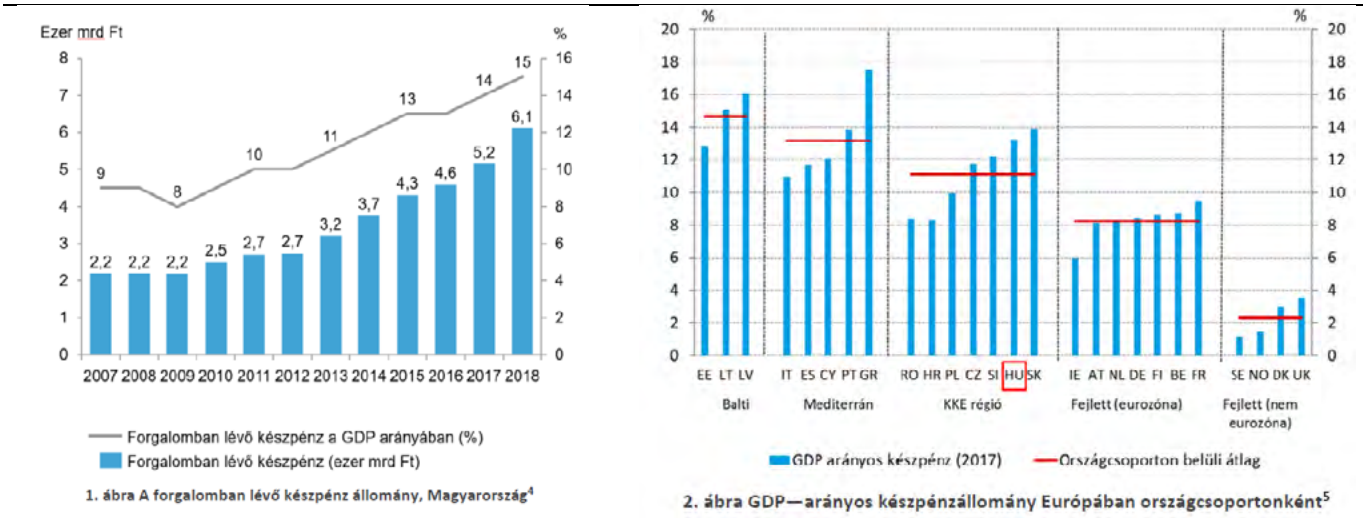

Figure 5: Cash (as non-working, aka dormant capital) versus working capital, Hungary vs the EU (2019).
Source: Association of Hungarian Banks
The left graph shows the cash in HUF billion in proportion to GDP in 2019. The right shows it in regional comparison.

Crowdfunding in Hungary has appeared, but yet underdeveloped. Launching services and breaking grounds as a small startup within an ecosystem-poor environment resulted in its valid yet slow growth. Without further analysis within this article, Figure 6 provides the first published overview of Hungarian platforms.

Table 2: Hungarian crowdfunding platforms.

Crowdfunding Platform (service since)	Type	No. of Campaigns	Capital raised
TokePortal.com (2020)	Equity, donation	25	HUF 1 bn
Adjukossze.hu (2013)	Donation, NGO	260	N/A
Sharity (2020)	Donation, CSR	N/A	N/A
Brancs (2022)	Reward	35	HUF 56,4M
Goood.hu (2015)	Donation	N/A	HUF 95,83M F

Platforms that ceased operation: Creativeselector.hu, Stagehive, Indulj. be, kezdheted.hu.

6. The king is dead, long live the crowd (funding, as a superdiscipline). Concluding remarks

Access to capital is a global demand. In 2024, private economy participants, from the cultural entrepreneur through SMEs to large incumbent companies, creative and innovative ecosystems are weaponed to reassemble the economy to make it more sustainable and more resilient. In countries where traditional, top-down approaches are prevalent and do not actively promote digital initiatives for the broader economy, bottom-up economic strategies can be energized by tapping into dormant capital directly from the population, a concept that the World Bank has already advocated for since 2013.

Before summarizing why, we should consider crowdfunding as a superdiscipline, Figure 7, an updated, enhanced version of the original diagram from the World Bank, shall be viewed. This revised diagram projects the creative power of the alumni-based ecosystem that ensures the driving power and the circularity of capital that will diffuse over the wider economy.

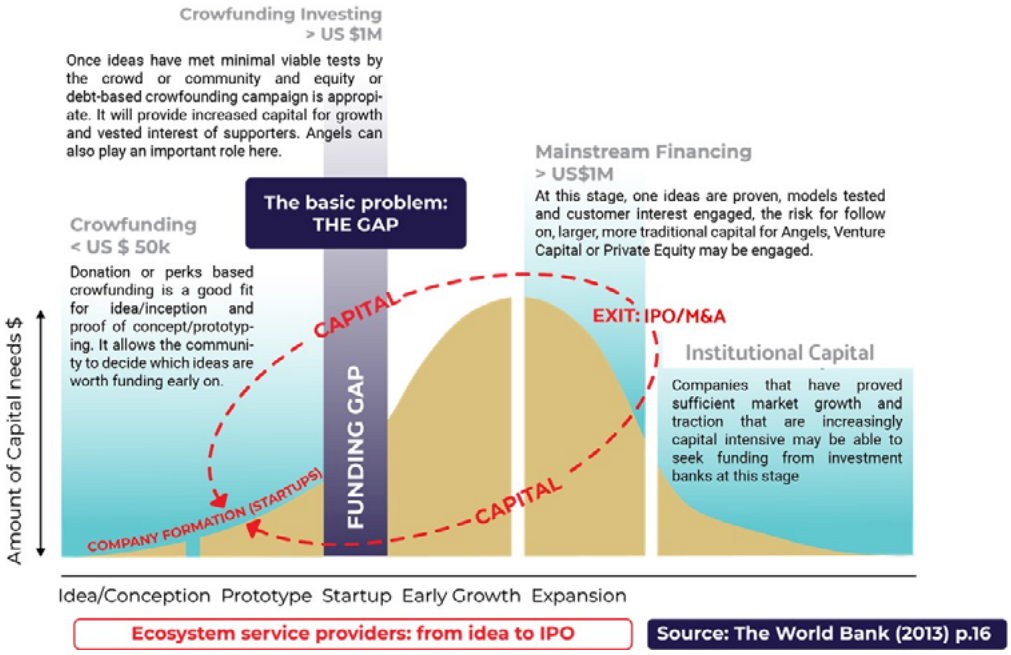

Figure 6: “Crowdfunding fills in the gap” – revised (Source: own figure, based on the World Bank figure).

Crowdfunding can be regarded as a "superdiscipline" because it integrates various elements of economy, culture, and technology. As a conclusion of this paper for the CCI entrepreneur, the value propositions 1-3 are introduced in this paper and are summarized.

1st: the meso-proposition is that crowdfunding is the most sustainable, most democratic funding bottom-up driver and, therefore, the most sustainable. More than a platform: an ecosystem-builder.
2nd: the macro-proposition concludes that ecosystems can transcend traditional economies based on interconnectedness and alumni cultures that contribute to capital circularity
3rd: the micro-proposition relates to participation in creating the campaign momentum and synchronizing the campaign communication with its prospective investors/backers.

Summarizing the multifaceted role of crowdfunding:

1. Interdisciplinary nature: Crowdfunding inherently involves finance, marketing, technology, and social networking.
2. Economic impact: crowdfunding mobilizes dormant capital, allowing it to flow into new and innovative projects. This influx of funding can stimulate economic growth, support new businesses, and create jobs.
3. Cultural impact: crowdfunding can contribute to a new type of ecosystem where crowd capital is fueled into CCI. As the network effect determines that successful platforms act as central marketplaces of capital, social capital, and knowledge capital and distribute these goods more inclusively and democratically, artistic projects might not otherwise receive funding, therefore, crowdfunding influences cultural development. This, in turn, serves as an inception point for spillovers into the wider economy and offers a real choice for the cultural entrepreneur between monopoly-, monopolistic, and democratic ecosystems.
4. Design innovation: crowdfunding allows designers to bypass traditional funding constraints, bringing innovative products directly to the market.
5. Regulatory aspects: Investment-based crowdfunding is regulated and fully passported within the EU, ensuring higher investor protection while raising the barrier of entry, leading to market consolidation and higher efficiency.

About the Author

Nora Szeles is an award-winning economist, university lecturer, and capital market professional recognized for her further contributions to entrepreneurship, project management, competitiveness, venture capital, and crowdfunding. Starting her career at the Budapest Stock Exchange, she pioneered the launch of derivatives trading and related research. Since 2014, she has been enrolled at MOME; earlier, she was a lecturer at Corvinus University and the International Centre of Banker's Education. Holding an MBA from Purdue University, USA, now in her PhD research, she is exploring crowdfunding as a transformative business model for entrepreneurs in the creative industry. As a practitioner, she is a co-founder of the first Hungarian crowdfunding service provider, Tokeportal. Winner of the Joseph de La Vega Award of the Demjan Scholarship.

Acknowledgements: I would like to say special thanks to (in alphabetical order):

DOI: 10.63442/LCQT2463

KEYWORDS | ENTREPRENEURSHIP THROUGH DESIGN, DESIGN PROCESS, STRATEGIC DESIGN, INNOVATION AND DESIGN, SOCIAL RESPONSIBILITY

ABSTRACT | This paper wants to present how our programs in Design support the next generation of Designers to be system game-changers, encouraging our students to work in an interdisciplinary way, combining tools and mindsets from different disciplines in project-based activities. Innovation is the temper of business design, but Innovation is not “only” in the solutions most of the time, it stays in the process of creating the right “environment” for ideas generation.

The paper presents how the Master in Business Design wants to create connections between the worlds of business and design, showing our didactic methods and, as applied research, some students’ projects that present new business models and strategies. Business Design, by definition, is a course that taps into different disciplines (e.g., marketing, design, sociology, law, etc.), creating an ever-changing didactic context and pushing us, as professors, to create an open context to push the spillover of ideas.

The projects were developed during our “Entrepreneurship Through Design” workshop, a laboratory-based course of two months in which our students, who come from different backgrounds, working experiences, and cultures, can create their ideas for new businesses from zero with the help of professors and professionals. We recognized the importance of creating a framework that is open and can accommodate the differences within heterogeneous teams and takes advantage of the strengths and potential offered by varied backgrounds and cultures. We aim to guide our students to become connectors, translators, integrators, or “chameleons.” During the workshop, they test themselves with new methods and tools, decoding and recombining them during the design process. They envisioned new scenarios, pushing the boundaries of the creative industry, but, in the end, they developed their ideas taking into consideration the real needs and feasibility of the design solutions.

The projects selected for this paper, both on Social Responsibility and on “Inclusivity and Overcoming the Stigma,” will show how important it is to contaminate our experience working with a transdisciplinary approach, sharing ideas, and pushing brainstorming activities. The outcomes, most of the time, are completely different from what one would expect from the addiction of the students’ competencies because the students tested themselves in new challenges, hybridizing their design process with new visions and tools. Still, most of all going through the process together as a team.

The main topics of this paper will be Entrepreneurship and Innovation in Design Culture, decoding, integrating, and recombining methods and tools into the Design process, and Inclusivity and Social Responsibility in new projects as Design goals.

FOCUS:

How Can We Push Innovation by Design?

- Decoding and recombining the design process in project-based activities.
- Supporting the next generation of designers to be game-changers.
- Encouraging our students to learn, decode and experiment.

CONTEXT:

Create a Fertile Context for Ideas Generation

The format:

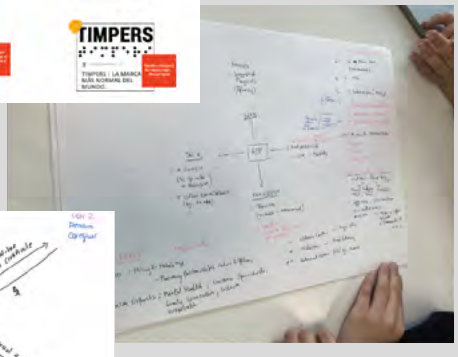
- Combining multidisciplinary teams
- Pushing the spillover of ideas
- Teaching different methods and tools
- Giving the structure of the workshop

CONTEXT: Multidisciplinary Teams

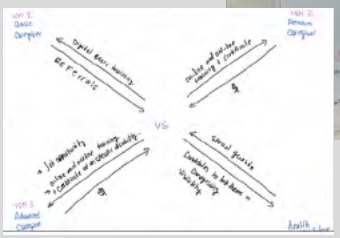
DISCIPLINE:

Business Design

Bridge between **Business and Design Studies**



With the aim of training “Hybrid Designers, Translators and Connectors”,
the **New Entrepreneurs**
through a **Transdisciplinary Approach**



HOW:

Entrepreneurship Through Design

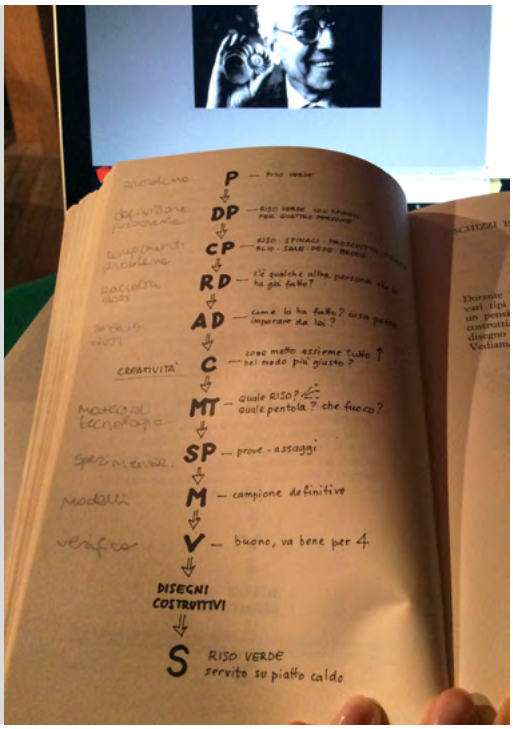
Project Based Activity:
students need to design strategies to launch in the market new business ideas, through means of design methodology, sensitivity and entrepreneurship culture with the help of professors and experts.

HOW:

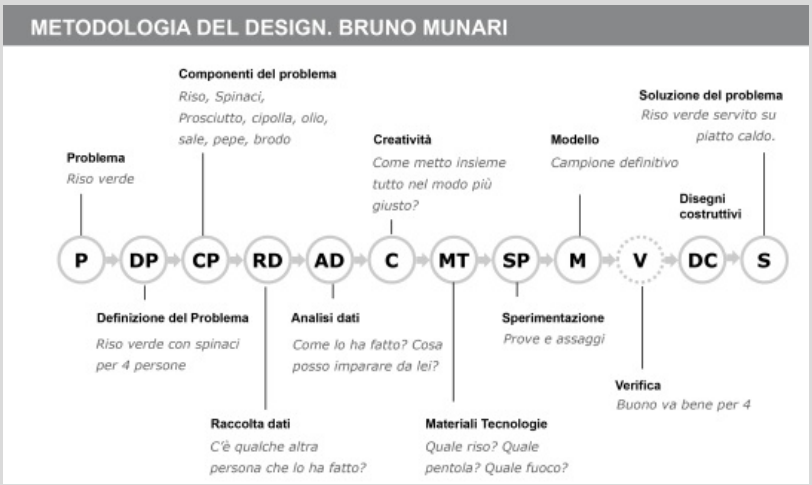
Entrepreneurship Through Design

The structure of our workshops:

5 weeks
4 design phases
Launch/MID/Final Presentation
8 Theoretical-Practical Lectures/9 Revisions
1 Project leader
Multidisciplinary teams
Company Led/ Internal challenge



HOW:



The Process! From Bruno Munari Method to us

"Il metodo progettuale non è altro che una serie di operazioni necessarie , disposte in un ordine logico dettato dall'esperienza"
"The design method is nothing more than a series of necessary operations arranged in a logical order dictated by experience"

Munari (2018, pp. 16–17)

HOW:

P // problem - Green rice
DP // definition of the problem - Green rice with spinach for four people
CP // components of the problem - Rice, oil, spinach, ham, onion, oil, salt, pepper, broth
RD // data collection – Is there anyone else who has already done this?
AD // data analysis – How did you do it? What can I learn from her?
C // CREATIVITY – How to put everything together in the right way?
MT // materials technology – Which rice? Which pot? What fire?
SP // experimentation – Tests, tastings
M // models – Final sample
V // verification – Good, good for 4
Construction drawings
S // solution – Green rice served on a hot plate

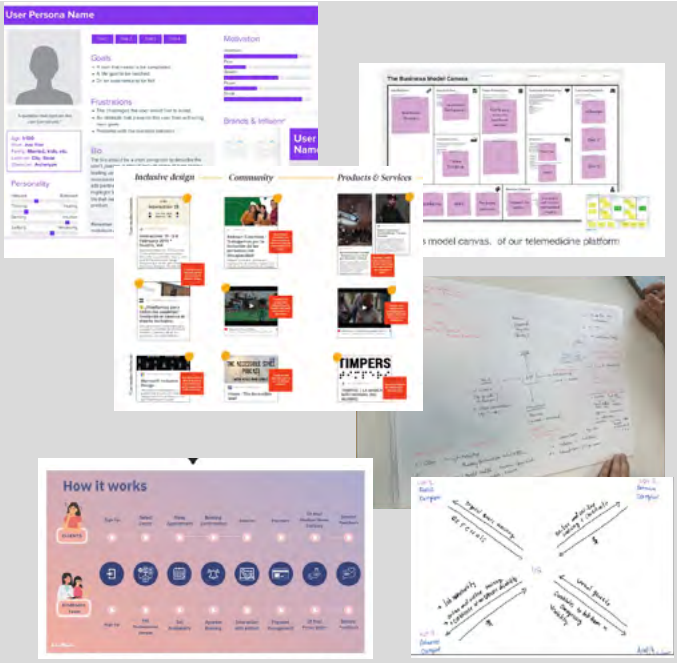
Munari (2018, pp. 62)

CREATIVE PROCESS:

Decoding, **I**ntegrating, and **R**ecombining **M**ethods and **T**ools into the Design **P**rocess

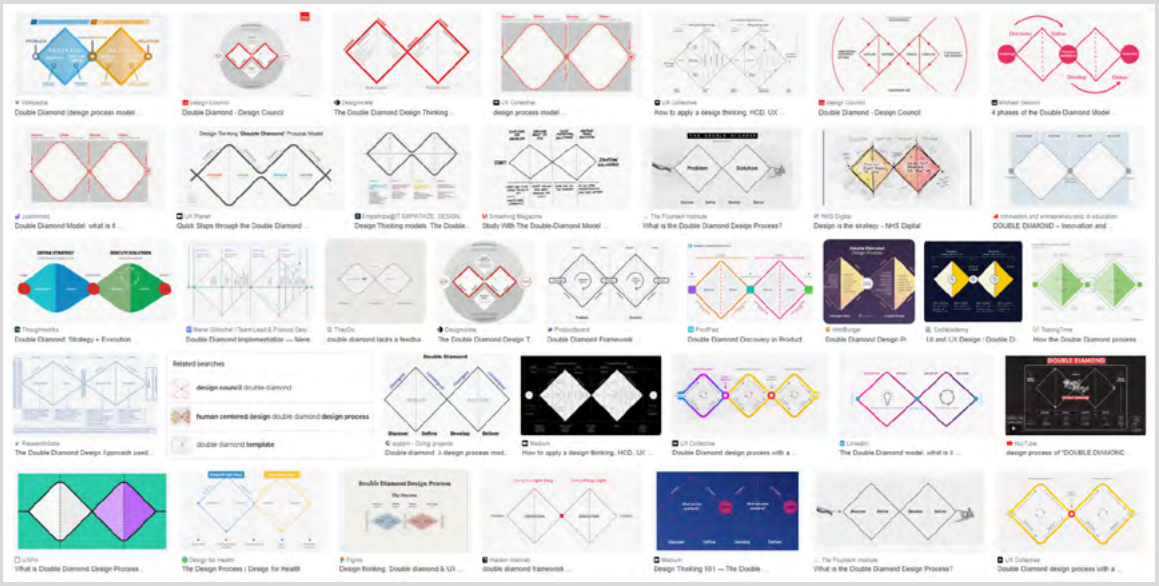
Starting from a Model. An example: the Double Diamonds process by the Design Council.

First and Second Phases: Discover and Define
customers profile analysis , customer journey analysis, competitors arena, market trends, market size, insights, critical success factors, ideas generation, …



The result is to create a design brief which clearly defines the challenge based on these insights.

Third and Final phases: Develop and Deliver
value proposition, business model, organizational structure, branding, feasibility aspects,
social and business KPI, prototyping, go to market strategy, communication strategy, business pitch(…)

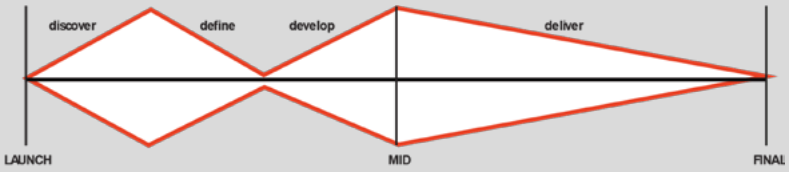


Cumulus Association

CREATIVE PROCESS:

Tools chosen based on the challenge and the Industry, trying to give different perspectives and methods to inform and nurture the design process.

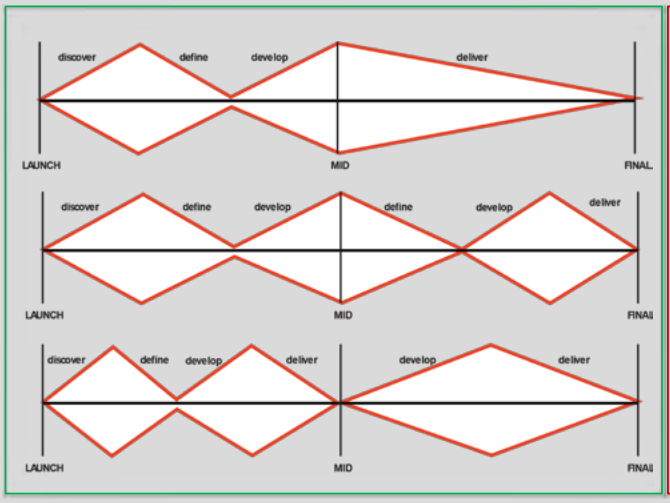
Cumulus Association



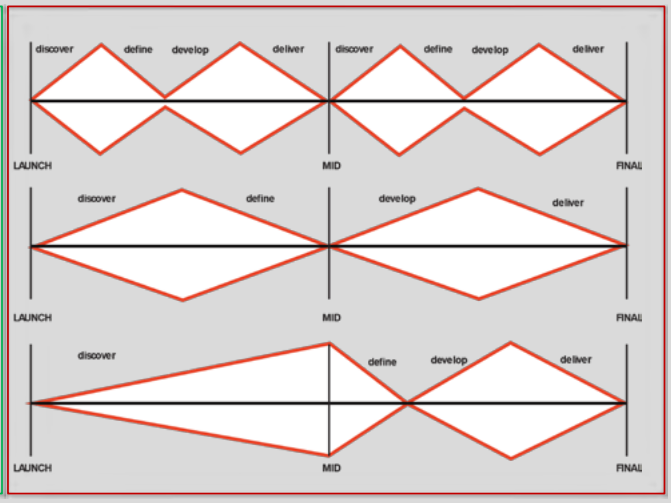
Cumulus Association

HOW: Double Diamonds Adapted within the Format of our Workshops

Entrepreneurship Through Design



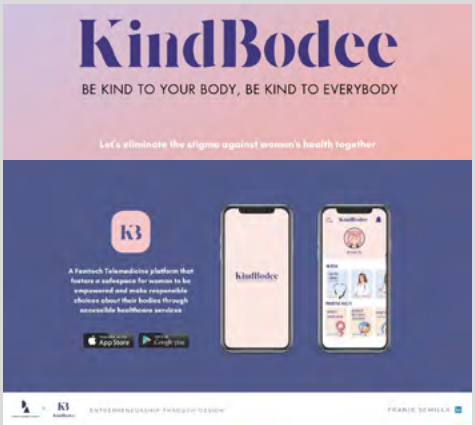
FROM THIS



TO THAT

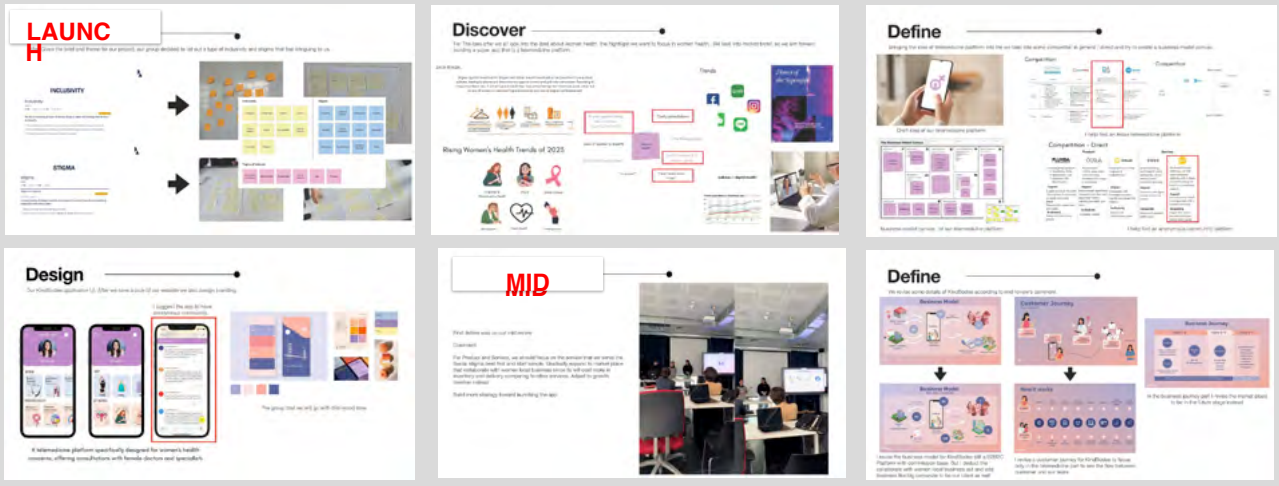
Cumulus Association

HOW: Examples of Emerged Patterns



☺ ☹

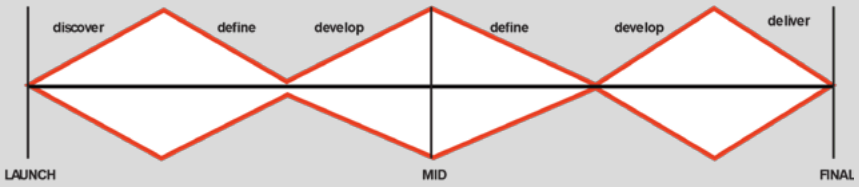
STUDENTS' PROJECT EXAMPLE:



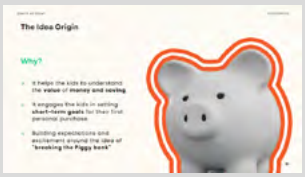
STUDENTS' PROJECT EXAMPLE:

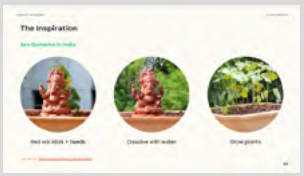
"This commendable project addresses a genuine societal concern, namely the stigma surrounding topics related to women in the Asian market. It amalgamates design and strategic elements within a compelling business model and service framework."
Academic Committee (internal and external faculty)

AN EXAMPLE OF OUR STUDENTS PROCESS BOOK: Learning and Decoding Methods, Design and Business Tools



AN EXAMPLE OF OUR STUDENTS PROCESS BOOK:
Learning and Decoding Methods, Design and Business Tools





Cumulus Association

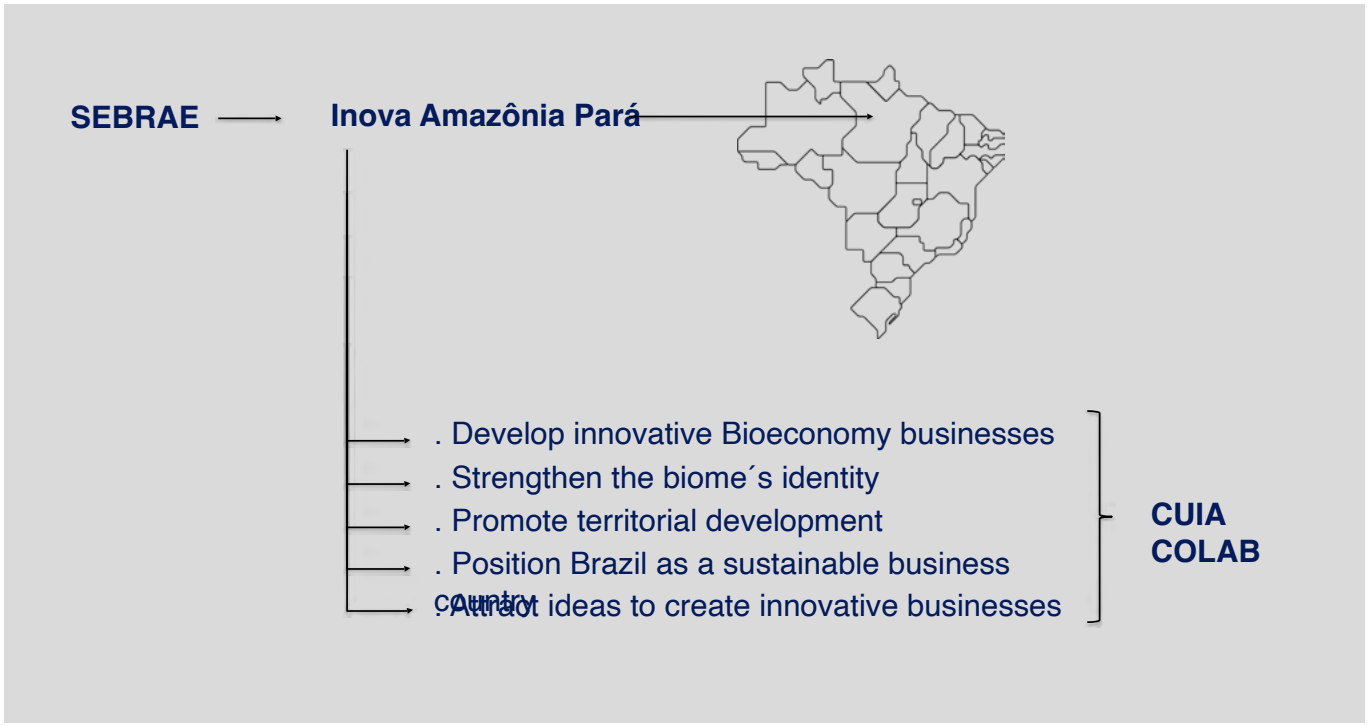
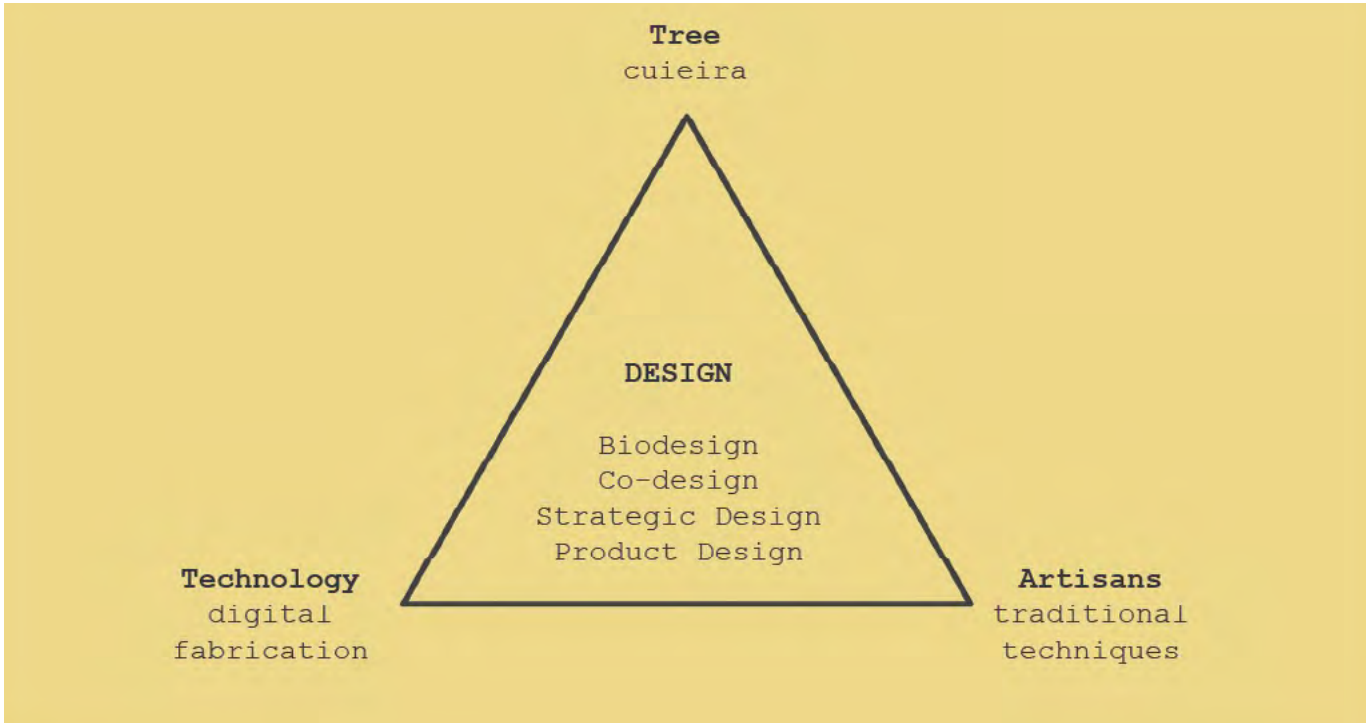
DESIGN IN THE CONTEXT OF BIOECONOMY: AN EXPERIENCE IN THE AMAZON FOREST.

Andrea Bandoni*, Carla Paoliello

Universidade de Lisboa, Faculdade de Belas-Artes, Portugal
* andreao@edu.ulisboa.pt



DOI: 10.63442/CXJD1023



KEYWORDS | BIODESIGN, BIOECONOMY, ANCESTRAL KNOWLEDGE, AMAZON FOREST, HUMAN AND NON-HUMAN INTERACTION

ABSTRACT | In 2021, SEBRAE, the Brazilian Service of Support to Small Entrepreneurs, initiated a call for projects entitled “Inova Amazônia Pará.” Situated in the northern region of Brazil within the context of the Amazon Forest, the primary objective of this call was to stimulate entrepreneurship and innovation through training for the development of products (commodities and/or services) or pioneering processes. The initiative’s goal was to facilitate the transformation of inventive concepts into sustainable enterprises, concurrently fortifying small-scale businesses that integrate novel technologies within sectors related to the bioeconomy. This study scrutinizes the Cuia Colab project (CCp), a design initiative selected as a startup under the abovementioned initiative. CCp centers around a regional item native to Pará: the cuias. They represent traditional artisanal objects crafted from an Amazonian tree, predominantly employed as bowls, vases, and containers. The fundamental objective of the Cuia Colab project was to integrate innovative practices into the cuias’ production process, leveraging their inherent qualities while preserving and promoting the cultural significance of these traditional Amazonian artifacts. It was a collaborative process between technology, artisanal communities, and trees facilitated through design.

Our research question is ‘How does the Cuia Colab project align with biodesign/bioeconomy intentions? Within this framework, Biodesign is a strategic collaborative approach that integrates living beings into developing alternative sustainable materials or products. Meanwhile, the Bioeconomy sustainably produces commodities and services in all economic sectors using biological resources, processes, and techniques. In CCp, we strengthened its Bioecology vision, prioritizing ecological processes, optimizing energy and nutrient utilization, and supporting biodiversity. Our methodological approach encompassed a literature review of these concepts to establish the theoretical/conceptual framework for the subsequent case study analyses. Then, the Cuia Colab process was described, delineating the intervention effects, particularly those that impacted the stakeholders (the artisan communities, the Amazon trees, and the forest – defined as a human and non-human interaction). We explored CCp activities and their correlation with the concepts already defined, providing a structure for critical reflections.

The Cuia Colab adopted a collaborative ethos with trees, viewing them as active agents that modified the initial design procedures. It also advocated forest vitality, fostering positive environmental and social impacts, departing from traditional industrial practices that mainly assert control over resources and prioritizing standardization. Therefore, it moved away from the maximized production pressure to corroborate with the forest’s economic viability. In conclusion, Cuia Colab exemplifies the imperative for reevaluating fundamental design principles and sustainability within the bioeconomic landscape. It can be seen as an example that illustrates the intricate balance between ecological preservation, socio-economic imperatives, and innovative design paradigms. In pursuing a bioeconomy enterprise imbued with ecological design principles, we suggest adopting bio-situated approaches prioritizing biodiversity over scalability. Additionally, it is imperative to demonstrate respect for and a deep understanding of the environment’s custodians and local knowledge systems. By prioritizing these considerations, designers can ensure their endeavors contribute to ecological sustainability while fostering harmonious relationships with local communities and ecosystems.

objects that grow on trees

How Does the Cuia Colab Project Align with Biodesign/Bioeconomy Intentions?

A strategic collaborative approach that integrates living beings into developing alternative sustainable materials or products.
(Myers, 2018)

A sustainable initiatives that establish, develop, and revitalize economic systems based on the sustainable utilization of renewable biological resources.
Bugge et al. (2019)

Research Methodology

1. Literature review on: _Brazilian Amazon Context
   _Biodesign and Bioeconomy
   _Human and non-human interactions
2. Cuia Colab project as a Case Study
3. Critical reflection, analyses and discussion
4. Conclusions

Artisan Silvane Maduro harvests a cuia in her backyard

Cuia Colab Project PIVOTAL QUESTIONS

_Is producing objects within a paradigm divergent from conventional norms feasible, as was coined by Ginsberg and Chieza's (2018) Biodesign expansive view or even the Bioecology vision by Bugge et al. (2019)?

_How will the project deliver tangible benefits for all stakeholders, including designers, artisans, trees, and clients, respecting Haraway's (2016) notion of 'companion species'?

_How can logistical challenges associated with an Amazonian product be handled ecologically?

_Should the Cuia Colab project persist solely as a business entity producing objects, as Silva et al. (2018) crave when addressing Amazon's potential for Bioeconomy?

_Are there alternative activities or pivots worth considering to embrace Watson's (2019) definition of design as a repository of sustainable practices responsive to environmental challenges?

CONCLUSIONS

. Situated Biodesign and Bioeconomy practices

. Biodiversity before scalability

. Social regeneration before economic growth

CUMULUS BUDAPEST 2024

SPECULATIVE PERSPECTIVES: NAVIGATING LIMINALITY.

Ákos Schneider*[a], Karina Vissonova[b], Ivica Mitrović[c]

a Moholy-Nagy University of Art and Design, Hungary
b Institute of Advanced Design Studies, Hungary
c Arts Academy, University of Split, Croatia
* schneider@mome.hu

This year's Cumulus theme began with the understanding that, in an age of polycrisis (Morin and Kern, 1999), refining existing practices is not enough; we must also critically reevaluate the foundational preferences and references of modern design at a systemic level. Our track aimed to gather diverse perspectives on speculative design, pushing the conversation beyond its traditional limits.

Designers have long been seen as problem-solvers, addressing a wide range of human needs and desires. However, as ecological and technological shifts challenge the market-driven, user-centered paradigm (Norman, 1988, Verganti, 2009), designers are increasingly exploring the complexities that arise when acknowledging that design's spatial and temporal dimensions extend far beyond the human scale. This change in perspective serves as a catalyst for new enquiries, in which design ventures into the realm of the speculative, the unconventional, and the transformative. Can design's role extend beyond its established boundaries? Can we consider distant futures, parallel timelines, or alternate pasts? Can we embrace a more expansive design philosophy? These questions guided our thinking about the track.

As co-chairs (Karina Vissonova, Ivica Mitrović, Ákos Schneider), we concentrated on highlighting speculative approaches that address more-than-human (Wakkary, 2021) considerations, broadening design to encompass the interconnectedness of humans, non-humans, the biosphere, and the technosphere. In addition, we explored post-speculative efforts aimed at evolving the practice to better tackle real-world challenges and foster bottom-up changes. Our intention was not merely to present speculative design as a method for imagining future scenarios but to foster a space for reflections that surpass the dominant human- and user-centered context.

The potential topics ranged from critical speculative design to unconventional timescales, material complexities, and the creative hybridization of digital or biological agents, extending to questions of design ontology. We received 70 full paper abstracts, of which 20 were accepted, and ultimately 11 made it into the conference program. Additionally, 19 submissions for slide decks, posters, workshops, and Format X were received, with 10 being accepted. All submissions underwent a double-blind peer-review process, with the involvement of international reviewers.

The selected submissions were organized into four sections. The Design Futures section (chaired by Michael Smyth and Karina Vissonova) explored speculative design practices with a focus on technological futures, space exploration, video game storytelling and urban food systems. The More-than-human Liminalities: Decenterings section (chaired by Ivica Mitrović and Ákos Schneider) speculated on design beyond anthropocentrism, addressing non-human agency, planetary futures, and artistic explorations of dark matter. More-than-human Liminalities: Entanglements (chaired by Ákos Schneider and Zsolt Miklósvölgyi) featured presentations on multispecies engagement, ocean-object network relations, and prototypes for more-than-human coexistence. Finally, the Beyond Speculative Design (chaired by Bruce Tharp and Ivica Mitrović) section featured discussions on activism, political rhetoric, and marginalized local futures. Among the workshops, some aimed to ethically evaluate the provocative gestures of discursive design, others focused on the commodification of emotions, and some examined the post-humanist aspects of digital imagery.

Based on the presentations and discussions, we have formed the overall impression that contemporary design culture (Julier, 2006) is often perceived as being in a liminal phase, where traditional methods are breaking down, while new approaches are yet to fully take shape. This state of transition is marked by uncertainty and challenges to professional identity, making critical speculation a particularly relevant method. However, liminality also implies that any emerging practice may be met with skepticism.

The tools of critical speculative design are being applied across diverse regions and contexts, now clearly reaching beyond gallery settings and educational spheres. This growth suggests that the genre has matured over the past decade, establishing itself within the contemporary design field. Nevertheless, as speculative design becomes more mainstream, there is a concern that it might be absorbed by the very systems it seeks to critique, leading to provocative yet ultimately safe and streamlined visions.

At the same time, post-speculative approaches are increasingly merging with social design and participatory methods. While speculative design is typically associated with envisioning speculative futures or alternative presents (Auger, 2013), there is a growing recognition of the importance of grounding these visions in present-day actions. However, questions arise about whether speculative design retains its critical potency when applied to direct problem-solving. This dilemma fueled the most intense discussions by the conclusion of the conference.

Choosing “more-than-human” as a theme for the speculative tracks proved to be successful. Not only did it generate a significant number of submissions, but it also became the focal point for two out of the four sections. This reflects a growing interest in the convergence of speculative design and more-than-human perspectives, acknowledging that our environment is shaped by more than just human actors—incorporating non-human entities such as animals, plants, or digital algorithmic systems into the equations of design.

In the era of polycrisis, a critical question arises: can we shift our focus from immediate user needs, user experience and interaction to consider other temporal dimensions and material interconnections? Recognizing scales and relationships that extend far beyond the human is, in itself, a speculative endeavor. This may eventually require stepping away from fiction-oriented speculative design towards systems thinking, potentially adopting post-designer-centered, post-user-centered viewpoints. Amid radical ecological and technological transformations, embracing these decenterings and moving beyond the immediate here-and-now is crucial. In this context, critical speculative design may not represent an endpoint but rather a starting

point for departure and decentralization. The shape of a post-anthropocentric design culture remains uncertain; we find ourselves in an in-between state, compelled to speculate.

KEYWORDS | FASHION GAMIFICATION, SPECULATIVE DESIGN, FASHION EDUCATION, NUDGE THEORY

ABSTRACT | The paper delves into the concept of fashion gamification, which blends elements of fashion and game design, explored as a speculative tool capable of constructing narratives and proposing alternative worlds. These imaginative scenarios present fresh perspectives for the evolving field of fashion in its digital transition, offering an alternative to the current unsustainable model due to its environmental and societal impacts. Such speculative approaches, which question possible futures and promote ethical, responsible design through new languages, are conditioning fashion education. This shift is geared towards training fashion designers capable of dealing with the complex languages of contemporaneity. The very idea of fashion design is undergoing a transformation, moving beyond the design of physical clothes, to express fashion imagery through different channels, both physical and digital. Through the analysis of a series of case studies, including a teaching experience conducted in 2023 at the Università degli Studi di Firenze, the paper will reflect on how speculative approaches to game design can enable fashion to address critical issues, discuss and propose alternative future scenarios, in which today's design decisions can shape tomorrow's realities.

1. Introduction

In her book *Adorned in Dreams*, Elizabeth Wilson (1985) pointed out the continuous 'confusions between the real and the non-real' that characterised postmodern fashion. Since then, fashion has evolved into a dynamic and fast-changing environment, fragmented into a myriad of contents spread across fashion communities on platforms and social networks (Franzo and Vaccari, 2021). The mediatisation of fashion (Rocamora, 2017; 2023) fits into the ecosystems proposed by Digital Culture (Gere, 2009; Miller, 2020) and refers to the transformative power of media (Cottle, 2006; Lunt & Livingstone, 2015) on the practices and experiences of fashion that are increasingly moulded by and for digital media in production, consumption, distribution, and dissemination. Defining 'digital' as a 'culture' – as is done with 'cyberculture' by Lévy (2001), 'information culture' by Manovich (2001), 'Internet culture' by Castells (2002), or 'virtual culture in cybersociety' by Jones (1998) – it suggests a shared set of norms, values, practices, and expectations among a group. Media and digital technologies introduce not just new tools, but new ways of acting and interacting, absorbing all aspects of human relationships and activities, becoming key in shaping social reality.

In the realm of contemporary fashion, digitisation is changing the ways in which companies engage with consumers and the nature of products that, while retaining the intrinsic identity values that characterise them, become immaterial, digital, and interactive. Hence, contemporary fashion increasingly finds itself exploring new channels in which to present its products, construct or reinforce imaginaries, and arouse the public's desire for immaterial, experience-based design outcomes (Särmäkari, 2021). Gaming, in particular, has been an area of particular interest for the fashion system for some years now, due to its ability to materialise worlds and shape expanded realities (Mascio, 2012; Gill, 2020), as demonstrated by the exponential growth of the sector (Amed et al., 2023).

The paper fits into this scenario, exploring fashion gamification – understood as contamination between fashion and game design – not only as a new language adopted by global brands to open up to new generations of consumers but also as a speculative tool capable of constructing narratives and proposals of alternative worlds. These are alternative presents for an evolving discipline in the context of its digitisation, a response to the current model considered unsustainable due to its impacts on the environment and society (Fry, 2009). These speculative approaches, which question possible futures and stimulate ethical and responsible design through new languages, are also conditioning fashion education, which is increasingly aimed at training fashion designers capable of dealing with the complex languages of contemporaneity. The very idea of fashion design is being reconfigured, and it is understood that it can no longer be limited to the design of physical clothes, but leads to the expression of fashion imaginaries through different channels, both physical and digital (Bogost, 2008; Smitheram, 2015).

The paper will therefore analyse the emerging role of gaming in the fashion system: both as a process of constructing virtual worlds, which contribute to giving shape and reality to the imaginaries of global luxury brands and as the outcome of speculative approaches that incentivise a paradigm shift. These two perspectives will be defined through a review of existing literature and investigated through the analysis of some significant case studies, including the experience conducted in 2023 at the Università degli Studi di Firenze. Students were asked to design a game conceived as an expansion of the activity of a fashion brand or institution, with the aim of generating greater public awareness of the impacts of fashion and, through the playful experience, conveying a message and incentivising a paradigm shift. The methodologies of speculative design (Auger, 2013; Dunne & Raby, 2013; Malpass, 2013) were combined with those of nudge theory (Walcher & Zotz, 2016; Thaler & Sunstein, 2008), leading students to imagine and design figural systems in which players gain knowledge and improve their behaviour.

The aim of this paper is, therefore, to reflect on how speculative approaches to game design can enable fashion to address critical issues, and discuss and propose alternative future scenarios, in which today's design decisions can shape tomorrow's realities. In this way, game design in fashion takes shape not only as the creation of imaginative experiences but also as a powerful tool for reflection and change.

2. Playing Fashion

The contemporary landscape is characterised by an increasing trend towards virtualisation and the gamification of various aspects of life, including communication, collaboration, learning, consumption, and entertainment. Advances in gaming technology have sparked interest in the use of digital games beyond traditional gaming contexts, exploring their utility in non-game environments (Alexiou & Schippers, 2018). Numerous studies have focused on the positive impact of gaming and the act of playing on developing critical cognitive, emotional, and social skills (Caponnetto et al., 2014; Granic et al., 2014; Qian & Clark, 2016). Furthermore, gaming has been explored as a means to stimulate specific behaviours, such as encouraging sustainable fashion consumption (Waydel-Bendyk, 2020). This approach is often referred to as gamification, which Huotari & Hamari (2017: 25) define as 'a process of enhancing a service with affordances for gameful experiences in order to support users' overall value creation'. In the realm of fashion, brands are leveraging gamification and game experiences to engage customers actively and personally, maintaining high levels of attention and proving economic advantages (Amed et al., 2023).

Gaming is a domain that is inherently rooted in digital interaction and immersive storytelling. It facilitates engagement in unique ways, offering immersive experiences through the development of innovative and customised customer journeys, fostering a creative and interactive narrative around a brand and its legacy. Through gaming, fashion finds a novel conduit to these audiences, offering experiences that are not only visually compelling but also culturally resonant and emotionally engaging. It also highlights the increasing importance of virtual environments in shaping consumer experiences and cultural trends. Much of this shift can be attributed to the habits of younger generations, who are increasingly investing resources, both in terms of time and money, into shaping their digital lives (Bain 2021).

This trend is prompting fashion brands to seize the opportunity to remain culturally relevant and experiment within digital ecosystems. From social media to the metaverse, fashion brands are teaming up with game developers to enhance their visibility among younger consumers. Furthermore, in the digital realm, avatars are perceived as reflections, extensions, or simulations of the player's identity, as discussed by Jin (2012) and Mancini & Sibilla (2017). This concept aligns seamlessly with the notion of 'possible selves' (Markus & Nurius, 1986) as the imaginative projection of a person's future identity or who they might become. This connection establishes a direct link to the social dimension of fashion. Avatars, akin to fashion products, enable users to explore different identities and styles, reflecting 'the me I want you to see' (Wood & Szymanski 2020). Consequently, avatars transcend their role as mere tools for personal expression and become mediums for social and cultural reflection, influencing perceptions and trends in the physical world. This highlights the increasing importance of digital fashion in shaping identity and belonging, marking a significant shift in how fashion is perceived and experienced in the digital age.

Recent collaborations between fashion brands and game developers have opened new avenues for designers in both fields to explore and define the roles of garments in digital environments (Gibson, 2021; Makryniotis, 2018). Such collaborations at the intersection of fashion and gaming can be broadly classified into three distinct categories, as identified by Alice Noris, Nadzeya Sabatini, and Lorenzo Cantoni (2023): 'Gamification in Fashion', 'Fashion in Games', and 'Fashion Games'. While the latter refers to video games where fashion is the central theme, such as characters to be dressed up, and fashion-related work activities, the first two categories, 'Gamification in Fashion' and 'Fashion in Games', are where fashion brands have particularly focused their attention, leading to innovative experiments in recent years. In 'Gamification in Fashion', brands integrate gaming principles into non-gaming contexts, enhancing the consumer experience with elements commonly found in video games. This approach has seen fashion brands create interactive campaigns, virtual worlds, and digital experiences that go beyond traditional marketing, offering customers an engaging and immersive journey that aligns with the interactive nature of games. 'Fashion in Games' involves the integration of fashion into video games that are not primarily about fashion. This has led to innovative partnerships where fashion brands collaborate with game developers to incorporate their designs and products into game worlds.

The burgeoning interest of fashion brands in gamification is deeply rooted in gaming's ability to build and bridge brand images to younger generations and to effectively market both digital and physical collections (Kim et al. 2012, Lau & Ki 2021; Ryder 2022). Additionally, games serve as platforms for brand co-creation experiences, allowing consumers to engage directly with brands, thus adding a novel dimension to customer involvement (Nobre & Ferreira 2017), transforming the online retail experience by creating interactive and immersive environments (Insley & Nunan 2014) and becoming a powerful marketing tool to deliver captivating digital experiences and extend their reach (Milanesi et al. 2022).

However, for the objectives of this contribution, it is particularly noteworthy to expand the discussion on hybrid practices in fashion and game design. Exploring the role of gamification as a tool to foster systemic change within the realm of sustainable fashion is critical to further contextualising and addressing existing research gaps (Joy et al. 2022; Milanesi et al. 2022). This leads to the emphasis on systemic change, which can be effectively catalysed through speculative perspectives. Such perspectives challenge the existing status quo and open up possibilities for new paradigms: Both the fashion and gaming industries, in this context, do not just mirror the world as it currently is, but rather focus on envisioning the world as it could be.

The issue of sustainability in fashion is complex and multi-dimensional, necessitating a comprehensive systemic change to adequately address its array of challenges. The present state of the fashion industry requires a profound reassessment of its foundational practices and structures (Fletcher, 2010). In this regard, speculative perspectives can be instrumental in envisioning alternative futures and challenging established norms, thereby paving the way for transformative changes.

3. Game as a Speculative Approach

The previous section analysed how gamification is a process adopted in recent years by many fashion brands in order to expand and diversify their narrative modes, strengthen their imagery and involve new customers, especially the younger generations. Now fashion gamification will be analysed as an expression of speculative design. The contribution, in fact, argues that the playful approach can represent a way of imagining alternative and desirable futures, and possible changes in visions and practices, with the aim of redirecting the present, which is considered unsustainable.

The definition of experimental and speculative design encompasses a wide range of practices that lie at the crossroads of design, activism, visual culture, and sociology, and that utilise inventions, fantasies, and uchronic stories beyond the promotional aims and objectives of industrial production. As James Auger (2013, p. 11), a researcher at the Royal College of Art, points out, speculative design is an area that is intertwined with critical design, discursive design, design probes, and design fictions, developing projects away from the commercial approach, promoting research through models and prototypes, using fiction to present alternative products, systems or worlds. As he points out, alternative presents are design proposals that utilise contemporary technology but apply different ideologies or configurations.

Speculative practices thus live in close relation to the future, a time that takes on different characteristics in relation to the present. Starting from a critical theory approach to design, Anthony Dunne and Fiona Raby considered design as a tool for creating ideas, stimulating 'social dreaming' and speculating on possible futures. In their manifesto, they contrasted design 'in the service of industry' with design 'in the service of society'; design that has 'fictional functions' with design that has 'functional fictions'; design that 'changes the world to suit us' with design that 'changes us to suit the world' (Dunne & Raby, 2009). Shifting design from the logic of profit to the space of reflection, they developed a theorisation of the future – or, rather, futures – from the theories of futurologist Stuart Candy. Three typologies are identified: the probable future, in which most designers operate and which only an extreme event can prevent from occurring; the plausible future, which could actually happen; and the possible future, which derives from critical reflection on the present and the imagination of alternative scenarios (Dunne & Raby, 2013, pp. 3-4).

These approaches provide challenging exploratory devices, 'as they allow the exercise of design to be removed from contextual and production constraints' (Quinz, 2020). However, as for practice, the resulting design outputs turn out to be often artifact-totems (intentionally) distant from industrial reality, and, for this reason, they may activate potentially revolutionary conversations and provocations, while not triggering a concrete transition to alternative futures stemming from everyday life. If it is true that 'we are creating the world to be understood, not merely understanding the created world' (Holt, 2016), design for transition seems to inhabit two complementary times: on the one hand, a progressive present, in which design acts; on the other, a near-future towards which design directs its action.

Picking up on the reflections of Jonathan Lukens and Carl DiSalvo of the Georgia Institute of Technology, therefore, a speculative approach makes it possible to verify the current limits of design and go beyond them (Lukens & DiSalvo, 2011, p. 26). Underlying this perspective is the idea that it is no longer possible to wait for the user-consumer to change, but that it is necessary to propose a new vision, a different design from what exists, and to rethink creative and production dynamics. A central role is attributed here to the designer, who once again plays an active role in redirecting design practices with the aim of building a sustainable future. As Cameron Tonkinwise (2015) points out, what designers make becomes the future we inhabit. This is the 'futuring' approach described by Australian design theorist Tony Fry (2009; 2010). In this way, designers are tasked with contributing to the identification of possible political alternatives to the current productive, social, and cultural scenario, which Fry has openly criticised as inevitably defuturing. Design is thus the catalyst for change, due to its influence and relevance to the economy, industry, technology, ecology, culture, community, and territory. In order to be in dialogue with contemporaneity, it has the task of considering and promoting the concept of 'sustain-ability', which includes the actions and skills needed to sustain life, cultures, ideas, imaginaries, the environment and people. Underlying futuring are practices of redirection, capable of shifting paradigms, materialising ideologies, shaping interactions between people, and delineating new scenarios (Vaccari & Vanni, 2021). The disciplinary contamination of design with future studies is not recent, but it seems to emerge in times of crisis.

While speculative approaches have been theorised in the field of design for some years, there is still limited research on speculative fashion, to which fashion gamification can be traced according to the reading proposed by this contribution. Speculative fashion, in fact, refers to a fashion that does not yet exist, hypothetical, but which could give real indications as to what fashion could be or could become (Vaccari & Franzo, 2022). It also shares a certain sense of urgency and social and political engagement. On the one hand, it allows one to think about and imagine the future; on the other, it represents a critique of present and current practices. This is the 'What If?' perspective, theorised by Caroline Evans and Alessandra Vaccari (2020) in their reflection on uchronic time in fashion, understood as alternative history, which allows for the construction of fantastic scenarios from facts and characters that really existed, and as invented time, but with real repercussions that can be revisionist or experimental. Uchrony involves imagined and fictional times and, as such, allows for the development of innovative thoughts and narratives. It encompasses a variety of phenomena, including not only utopian legacies, when a fashion brand reinvents its history, and trendforecasting, when predictions of the future are commercially motivated, but also fashion gamification, made possible by digital fashion image-making.

The framework proposed by this contribution introduces an additional element that helps to understand and interpret the phenomenon of fashion gamification: the nudge theory, characterised by methodologies geared towards modifying people's behaviour through play and curiosity (Cai, 2019). As will be analysed in the following chapter, some examples of fashion gamification use the vector of play to improve user-consumer behaviour and bring about a better reality. In their bestselling book Nudge: Improving Decisions about Health, Wealth and Happiness (2008), economist Richard Thaler and legal scholar Cass Sunstein argue that simple 'nudge' techniques can help us break bad habits and make a range of choices in our own best interests (see also Sunstein, 2015; Thaler, 2015; Thaler and Sunstein, 2003a, 2003b, 2006). Thaler and Sunstein argue, however, that behavioural techniques have the potential to positively transform a wider range of societal problems, from racism, to suicide, to climate change (see also Halpern, 2015). These kinds of indirect prompts are much more effective in getting people to modify their habitual behaviour than more heavy-handed approaches.

4. Case Study Analysis

Some case studies will now be analysed to illustrate the two main trajectories characterising the relationship between fashion and game design. Together, these cases illustrate the diverse strategies fashion brands are employing to navigate the evolving landscape of digital engagement, showcasing the potential of gaming as a medium for innovative brand storytelling, audience expansion, and speculative design in fashion.

4.1 Louis Vuitton and League of Legends

In a pioneering instance of cross-industry collaboration, the year 2019 witnessed a landmark partnership between the luxury brand Louis Vuitton and Riot Games, the developer behind the esports phenomenon *League of Legends*. This collaboration signified a groundbreaking convergence between the world of high fashion and the realm of competitive esports, reflecting an innovative melding of distinct industry spheres. The collaboration encompassed multiple facets, beginning with the creation of a trophy case for the *League of Legends* World Championship. The finals of this esports event were held on November 10, 2020, in Paris, providing a global stage for this unique partnership, marking a significant cultural and commercial intersection, blending the traditional artisanship of a high-end fashion brand with the dynamic world of competitive gaming. The collaboration between Louis Vuitton and Riot Games reached a notable milestone with the unveiling of the *Louis Vuitton x League of Legends* capsule collection, designed by Nicolas Ghesquière in partnership with Riot Games. This collection, focused on womenswear and genderless garments, stands as a tribute to Qiyana, a female protagonist in League of Legends. Ghesquière had previously designed Prestige skins for Qiyana, featuring the signature aesthetics of Louis Vuitton, blending the world of high fashion with digital gaming culture.

This capsule collection represents a significant fusion of luxury fashion and virtual gaming iconography, demonstrating how a fashion house can effectively translate its design ethos into the realm of esports. By focusing on a female character from the game, the collection not only celebrates the influence of digital characters in contemporary culture but also showcases the potential of esports and gaming platforms as powerful channels for fashion expression and storytelling. The partnership between Ghesquière, Louis Vuitton, and Riot Games exemplifies a forward-thinking approach to design, where the boundaries between the virtual and the physical, the digital and the couture, are seamlessly blended.

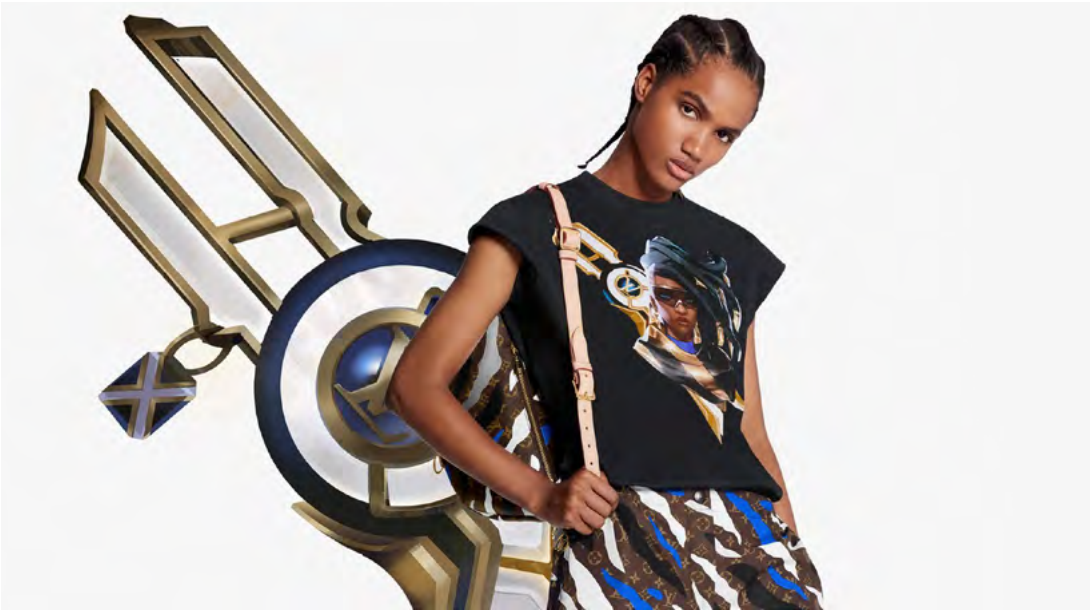

Figure 1. Louis Vuitton x League of Legends collection, 2019.

4.2 Balenciaga Afterworld

The Balenciaga *Afterworld* project represents a significant venture at the intersection of high fashion and digital gaming. In this initiative, Balenciaga extended its creative expression into the realm of digital gaming. Afterworld is an ambitious and immersive gaming experience that transcends the traditional bounds of fashion presentation. Set in a speculative future, *Afterworld* not only showcases Balenciaga's collection but also invites players into a narrative-driven journey through meticulously designed virtual environments. The game is set in the year 2031, offering a dystopian yet captivating vision of the future. Players navigate through various levels, each one of them specifically designed to reflect the thematic elements of Balenciaga's collection and the broader narrative of the game.

The integration of fashion into this gaming experience is seamless and intrinsic, with the game serving as a platform for showcasing Balenciaga's designs. The virtual avatars within the game are adorned with pieces from the collection, allowing players to interact with and experience the fashion in a dynamic, three-dimensional space. This approach to fashion presentation is groundbreaking, blending storytelling, gaming, and fashion design into a cohesive and immersive digital experience. *Afterworld* is not just a game; it's a visionary exploration of the possibilities of fashion in a digital context. It represents a paradigm shift in how fashion can be presented and experienced, moving beyond conventional runways and lookbooks to interactive and narrative-rich digital platforms. This project exemplifies how luxury fashion brands can leverage digital technology to create novel and engaging experiences that resonate with contemporary audiences, particularly those familiar with and immersed in digital gaming cultures.

Figure 2. Balenciaga Afterworld, 2021.

4.3 Max Mara Coat Adventures

This is a game within the Roblox platform, in which it is possible to witness the integration of immersive experiences and educational content in the realm of fashion gaming. This game, launched in 2023, proposes a virtual world, characterised by an imaginative landscape where traditional elements of fabric and textile manufacturing are reimagined: meadows transform into expanses of fabric and trees as colossal spools. Here, players navigate a rollercoaster carrying iconic 101801 coats, illustrating a creative interplay between fashion elements and gaming dynamics. *Max Mara Coats Adventure* is segmented into three primary zones: *Pattern Lab*, a virtual tailoring workshop; *Color Parkour,* a navigational challenge focused on collecting colour spheres that align with the brand's colour palette; and *WunderKammer*, a fantastical labyrinth co-created with the artistic collective Atelier dell'Errore from Reggio Emilia. In this section, participants can engage in the creative assembly of mythical creatures, known as 'daimons', which accompany the avatars of the players, adding a layer of personalisation to the user experience.

A relevant aspect of this gaming environment is its educational dimension. *Max Mara Coats Adventure* offers not only an engaging gaming experience but also educational insights, ranging from historical and cultural information about the textile industry to collaborative challenges that promote collective achievement within the game. This case study is a significant example of how fashion brands can expand their outreach into digital gaming platforms, effectively merging brand promotion with educational and community-building objectives. The game serves as an innovative model for how fashion can be recontextualised within digital environments, providing insights into the potential future trajectories of fashion branding and consumer engagement.

4.4 SUNNEI Canvas

SUNNEI Canvas, an initiative by the Italian fashion brand SUNNEI, combines traditional elements of design with cutting-edge digital technology. Launched in July 2020, the *SUNNEI Canvas* collection introduced a gender-neutral clothing line, presented through Computer-Generated Imagery (CGI) models. This approach was particularly resonant at a time when the world was adapting to life during the pandemic, with many people confined to their homes. On SUNNEI's digital platform, top retailers were given the opportunity to personalise their orders, allowing them to modify the design, shapes, and even the materials of each creation. This initiative marked a significant step towards reducing environmental impact, as it eliminated the need for physical samples. Moreover, it enhanced the direct relationship with buyers, allowing them a greater degree of involvement in the design process. This approach not only reflected Sunnei's commitment to sustainability but also its dedication to fostering stronger connections with its retail partners.

In further advancement of this concept, the *SUNNEI Canvas* collection went into the digital realm with the Fall/Winter 2021 presentation. SUNNEI elevated the digital aspects of its work by showcasing the collection within a video game environment. This platform featured 3D characters performing in a paradoxical, never-ending game, offering an avant-garde and limitless approach to fashion presentations. In this virtual setting, ten avatars were available for customisation with different outfits from the FW21 collection. Each avatar could transition through various looks, symbolising the continuous cycle of fashion trends.

Figure 3. SUNNEI Canvas, 2020.

4.5 Metamorphic Fashion Design

Metamorphic Fashion Design, conceived in 2020, is an educational project undertaken at the Università degli Studi di Firenze in collaboration with Fondazione Sistema Toscana – Manifatture Digitali Cinema. This initiative, born in the midst of the global pandemic, seeks to address the pressing issues of our time by

merging the worlds of fashion and gaming, particularly by using gaming as a tool to explore central themes in contemporary fashion. At the heart of *Metamorphic Fashion Design* is the exploration of protection as a concept, drawing inspiration from the natural world. The project delves into phenomena such as mutation, mimicry, symbiosis, and collaboration, mirroring these natural processes in a digital 'forest' setting. This environment serves as a backdrop for an array of unique characters, including grasshoppers, peacocks, bees, and aliens, which transcend traditional storytelling through metaphysical narratives and conceptual elements. The characters in this project are adorned in garments designed and adapted to the game context by students from the Università degli Studi di Firenze. The designs, which emphasise low environmental impact, no-gender principles, and multi-layered fashion, bring the narrative to life. They form a virtual collection that not only highlights sustainability and adaptability in fashion but also demonstrates the potential of digital technology in fashion design.

Metamorphic Fashion Design exemplifies the intersection of digital technology, environmental awareness, and cutting-edge fashion design within an educational framework. The project aims to redefine how fashion is presented and perceived, integrating contemporary themes and challenging conventional fashion paradigms. It showcases how digital platforms, used as an educational tool, can reorient the way fashion is taught, communicated, and experienced, making it a valuable case study for contemporary fashion education. This approach reflects the evolving needs of the fashion industry and the importance of integrating innovative methods like gaming into fashion education to address central themes in the contemporary fashion landscape.

Figure 4. Metamorphic Fashion Design, 2020.

4.6 Game Design Course

Concluded in January 2024, the Game Design course within the MA Degree Course in Fashion System Design at the Università degli Studi di Firenze was conceived as an educational journey, merging the worlds of digital gaming and fashion. In this course, students were challenged to design games as extensions of fashion brands or institutions, aiming to increase public awareness about the fashion industry's impacts. The course's approach combined playful experiences with educational content to convey meaningful messages and encourage behavioural changes, as well as a shift in perceptions of fashion among brands, institutions, or consumers. Throughout the course, students explored a speculative design approach to game design, allowing them to envision and create future scenarios, challenging the existing norms and practices of the fashion industry. In addition, the course incorporated nudge theory principles, to subtly

guide player behaviour within the game environments. This integration of nudge theory encouraged the development of games that not only inform but also influence player behaviour towards more responsible and sustainable fashion practices. The culmination of the course saw the creation of 'figural systems' – interactive and immersive game environments where knowledge acquisition and behaviour improvement were key objectives. These systems were designed to be both informative and engaging, offering players a platform to learn about the fashion industry's impact while enjoying a compelling gaming experience. The students' final projects demonstrated a deep understanding of how game design could be utilised as a powerful tool for communication and change within the fashion industry. Moreover, the course highlights the potential of integrating game design with fashion studies. It showcased how digital platforms could be effectively used to address critical issues in the fashion industry, offering a novel way to educate and engage both students and audiences about sustainability and responsible consumption.

4.7 Discussion

The collaboration between Louis Vuitton and *League of Legends* exemplifies the experimental efforts made by fashion brands to engage new audience types, such as esports players, showcasing how luxury fashion brands are reaching out to the gaming community. Meanwhile, *Max Mara Coat Adventures* represents a case of creating digital worlds that intersect brand communication with edutainment, reflecting an innovative approach to brand storytelling through in-game immersive digital experiences. Balenciaga's Afterworld project offers a profound insight into the interpretation of fashion gamification as an act of speculative design. This case highlights how fashion brands can use digital platforms not only for marketing but also for envisioning and presenting speculative futures. *SUNNEI Canvas* exemplifies a pioneering approach to fashion presentation and consumer engagement. By integrating digital technology and interactive gaming elements, SUNNEI has not only expanded the boundaries of fashion marketing but also illustrated the potential for digital platforms to revolutionise the way fashion is consumed and experienced.

Adding to this discussion of case studies, *Metamorphic Fashion Design* explores the use of gaming in fashion education as a tool to address key themes in contemporary fashion, such as environmental sustainability and adaptability. This project offers a fresh perspective on fashion communication and demonstrates the power of digital storytelling in fashion education. Furthermore, the Game Design Course underscores this educational approach, where students design games that extend the activities of fashion brands or institutions, aiming to increase awareness and encourage behavioural changes in the context of fashion's impact through speculative approaches.

These case studies collectively illustrate the evolving landscape of fashion in the digital era, underscoring the significant potential of gaming and digital platforms as influential tools for creative brand storytelling, broadening audience reach, and emphasising the importance of speculative approaches in fostering a shift towards sustainability in fashion. The array of strategies adopted by these fashion brands, along with the educational experiences conducted at the Università degli Studi di Firenze, marks a shift into a new form of Digital Game, where responsibility and social consciousness are proportional to the complexity of the virtual reality created.

This evolution represents a shift in the fashion industry's approach to engagement, moving beyond mere entertainment to embed deeper social and environmental messages within the gaming experience. The case studies demonstrate how fashion brands are effectively using digital platforms not just for marketing, but also for conveying contemporary relevant messages about sustainability and responsible consumption. The educational experiences at the Università degli Studi di Firenze, in particular, highlight how academic institutions can play a pivotal role in shaping the future of fashion by integrating gaming and digital technologies into their curricula.

5. Conclusions

In conclusion, this article aimed to capture the essence of how the fashion industry, through its engagement with digital and gaming platforms, is adopting speculative approaches to tackle complex, multifaceted challenges. As highlighted by Dunne and Raby (2013), this approach 'thrives on imagination and aims to open up new perspectives', creating spaces for discussion and debate about alternative ways of being. This is particularly evident in the ways fashion has embraced gamification and speculative design, moving beyond traditional paradigms to foster engagement, community building, and the strengthening of brand narratives.

The potential of gamification to motivate individuals to share knowledge, become part of a community, and reinforce the imagery of a product or brand has been increasingly recognised (Kwon et al., 2015; Swacha, 2015; Silic and Back, 2017). This recognition aligns with Bergonse's (2017) definition of a videogame as a mode of interaction within a meaningful fictional context, sustained by emotional attachment. This engagement transcends the mere consumption of fashion, involving players in a narrative that intertwines the virtual with the real. Hence, understanding fashion's attempts to engage with newer, younger audiences, such as gaming communities, requires exploring the mechanisms of fiction, blending the imaginary with reality, and creating narrative planes where fantasy, suggestion, and adventure intersect with real-life experiences.

The digital world, in its production of dematerialised identities, feeds on and contributes to new values and practices (Rocamora, 2023). The close link that is consolidated between physical and digital reality can be more easily grasped if we move away from understanding 'virtual' as a term exclusively referred to cyberspace (and thus as something illusory that differs radically from physical reality) to embrace the term in its original meaning, i.e. as something 'real without being actual, ideal without being abstract' (Proust as cited in Rob Shields, 2005) in other words as a 'plane of immanence', as a site of generative potentiality that is delineated through actualisations in daily life (Deleuze, 2005).

Thus, the cases studied here – from Louis Vuitton's collaboration with *League of Legends* to *Max Mara's Coat Adventures*, Balenciaga's *Afterworld*, *SUNNEI Canvas*, *Metamorphic Fashion Design*, and the Game Design Course at the Università degli Studi di Firenze – demonstrate a shift in fashion towards a more immersive, interactive, and imaginative realm. These initiatives highlight how fashion capacity in crafting narratives, and experiences, and engaging with contemporary societal issues, particularly sustainability. The integration of digital tools in higher education, as explored by Bain (2021), Bertola & Colombi (2021), Särmäkari (2021), Tepe & Koohnavard (2023), and Varra (2021), presents opportunities for creating alternative fashion-related experiences in digital and hybrid spaces. This approach prepares future digital fashion designers to break from traditional norms and develop practices and values unique to digital environments (Logaldo, 2016; Särmäkari & Vänskä, 2022; Thiel, 2017).

Ultimately, by embracing gaming and digital technologies, the fashion industry is not only expanding its reach and reshaping its narrative techniques but is also significantly contributing to broader cultural and social discourses. This transformative phase in the industry signifies fashion's evolution into a medium for storytelling, community engagement, and addressing global challenges, redefining its role in contemporary society.

ABSTRACT | Rhetorical discourse within the political sphere appears evermore meaningless and impotent to the complex challenges within contemporary society. This is partly due to the influence of social media, changing the dynamic of communication, and the limitations of traditional rhetorical devices to persuade and communicate new or original ideas. Through this research, we explore how speculative and critical design methods might be utilised within political discourse to communicate the unfamiliar by co-opting the familiar rhetoric from the past or present. We term this approach counter-rhetorical design, a subgroup of speculative design that utilises past failed rhetorical arguments as a framework to propose implementable solutions based on the original objectives represented by the rhetorical device. The results from this research project consist of two case studies created using the counter-rhetorical design approach. It concludes with an outline of future opportunities and further research which might enable new modes of political persuasion, or methods to bring specificity and content to the future political discourse.

1. Introduction

Traditional rhetoric in the political arena appears increasingly meaningless and ineffective in addressing the wicked problems that confront us globally. This aligns with the declining public trust in politicians, which Ipsos (2023) reports is at its lowest in four decades.

This paper proposes that social media's instant, omnipresent, and diverse feedback loops have negatively impacted how the public perceives political rhetoric. Digital media, as pointed out by Flanagin & Metzger (2017), makes it difficult for people to assess the credibility of the available sources due to their sheer number and the challenges of verifying their authors' intentions and expertise, reflecting a public credibility erosion in political speech. Moreover, Coe's (2015) concept of narrowcasting, where social media enables the possibility to target specific political messages to specific groups, not only alters the delivery of political messages but also fosters political division and scepticism towards political statements outside one's social media echo chamber. Despite its long-standing role in political engagement since ancient Greece, political rhetoric must be reconsidered and updated to suit our intricately connected modern society.

This paper aims to show how contemporary challenges associated with political rhetoric might be addressed by utilising speculative design methods and tools, thereby facilitating the development of concrete and impactful political propositions. Here, we introduce the concept of Counter-rhetorical design. This approach borrows from speculative design methods and uses counterfactual conditionals—hypothetical scenarios describing situations and their outcomes—to show what would have happened under different circumstances.

The counter-rhetorical design aims to unveil the fallacies within political rhetoric about ineffective, deceptive, or manipulative ideas, typically propagated by those in positions of power or influence, political figures, or movements, or by advertisements or campaigns. Borrowing from James Augers' notion of 'alternative presents' (Božanić, S., & Bertalanič, P. 2019), it seeks to envision how the world might look if these ideas had come to fruition. Counter-rhetorical design is not a futuring device but a fictional present generator. It challenges historical political rhetoric by illustrating its unfulfilled promises through speculative 'present-day' scenarios.

This paper presents two counter-rhetorical design project case studies: 'Trickle-Down' and 'Level Up.' Trickle-Down revisits the 1980s, proposing a new function of money that makes income tax redundant by directly redistributing wealth between people's banks or saving accounts. This system and its associated devices reflect the principles of classical liberalism and free-market capitalism advocated by Friedrich Hayek and popularised by the rhetoric of Margaret Thatcher and Ronald Reagan. Conversely, the 'Level Up' project introduces a variable geographical tax rate for a new central bank digital currency (CBDC pound), based on the 'Levelling Up' rhetoric used by Boris Johnson's government to gain power in the 2019 general election.

In summary, this study's practical design work and methodologies highlight the significance of critical thinking and design in lending tangibility and specificity to political discourse. This approach offers valuable insights and tools for future political endeavours aimed at exploring and trialling new ways of engaging with politics, formulating policies, and communicating ideas.

2. Broken Rhetoric – Contextualizing the Issue

This section outlines a brief history of the classic rhetorical tool and questions its effectiveness in our social media-dominated society. When rhetoric is free of restraint or review, is it time to rethink its use to frame our political choices?

Rhetoric is a tool for persuasion that has stood the test of time. Most scholars accept that rhetoric can be traced back roughly 2500 years to the sophists in Greece in the 5th Century BCE. (LEGGETT, 2012) However, it was Aristotle who helped formalise rhetoric.

> "…these three means of effecting persuasion. The man who is to be in command of them must, it is clear, be able (1) to reason logically, (2) to understand human character and goodness in their various forms, and (3) to understand the emotions-that is, to name them and describe them, to know their causes and the way in which they are excited." (Welldon, 1886, p.12)

According to Herrick (2017), opinions on rhetoric have been divided since its foundations. Philosophers such as John Locke, who qualified it as deceptive, or Friedrich Nietzsche, who coined it as a "gentle reproof", helped tarnish rhetoric's image. However, Herrick explains, we are at a cultural juncture where the study of rhetoric is gaining recognition for its contribution to human communication.

Good and bad rhetorical arguments have always existed. An example of a good and influential rhetoric would be Martin Luther King's 'I Have a Dream'. In his speech, aspects of Aristotle's principle of rhetoric were effectively met, using a wide variety of rhetorical tools and "rely[ing] heavily on "loaded" language geared towards engaging the emotions of his audience" Washington (1993). However, demagogues also propose bad rhetorical arguments that utilise people's desires or prejudices. This dichotomy shows how a "longstanding association with persuasion has been at the heart of the conflict over whether rhetoric is a neutral tool for bringing about agreements or an immoral activity that ends in manipulation"—Herrick (2017) p. 4.

The prevalence of good and bad actors in rhetoric might not have changed much over the centuries, but its methods of communication have. Traditional media (radio, television, or printing press) has often relied on verification and a consensus of experts to determine the truth of specific claims, often relying on journalistic standards, editorial processes, and fact-checking practices (at least in democracies). For example, the Code of Ethics of the Society of Professional Journalists set guidelines for "seeking truth and providing a fair and comprehensive account of events and issues", helping to reduce opportunities for demagogues to exploit.

With the advent of social media, all those brakes came off -the friction associated with editing a paper, commissioning a TV report, or travelling to deliver a live radio broadcast- is gone. The institutional control and self-regulating mechanisms from the media outlets and the broadcasting standards have been sidestepped, along with the expert's analysis and viewpoints that add perspective. The way social media works conduce to "low barriers to entry and reliance on user-generated content […] undermin[ing] the reputation mechanisms that serve to guard the quality of information of traditional media outlets" Zhurayskaya et al. (2020). Hence, facilitating and maximising the effect of unethical rhetoric practices.

In the light of social media and our highly connected society, rhetoric has exploded and arguably in doings so also become meaningless. Exemplifying this are a couple of tweets from Donald Trump's tweets during his tenure as U.S. president, during which he sent roughly 30 tweets per day. (Coles, 2020):

> I will be leaving the great Walter Reed Medical Center today at 6:30 P.M. Feeling really good! Don't be afraid of Covid. Don't let it dominate your life. We have developed, under the Trump Administration, some really great drugs & knowledge. I feel better than I did 20 years ago!

2.1 Broken Rhetoric – The Act of Countering

In the previous section, we argued that traditional political rhetoric has become ineffective in the modern digital era, where social media's influence leads to decreased public trust in political communication. In this section, we introduce the notion of counter-rhetorical design, a design tool that can be employed to increase public trust in political messages.

As political discussions shift to social media platforms, rhetoric must evolve. It must become more concise and immediate, aiming to engage a diverse audience with clear, universally comprehensible language. Social media's intrinsic characteristics demand that rhetoric be handled as a form of direct communication between individuals (Dannagal et al., 2023).

On the other hand, the essence of political rhetoric must navigate within the boundaries of what is generally deemed acceptable by the public. Most politicians aim to secure election or re-election, so their rhetorical approaches must align with the **Overton window*** (Mackinac Center for Public Policy), ensuring their messages resonate within the permissible spectrum of public discourse.

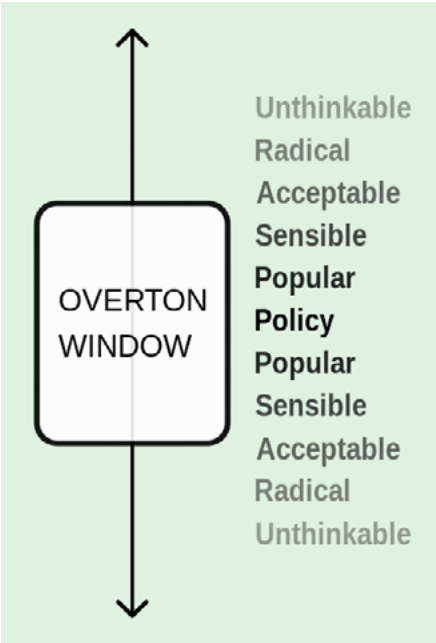

Figure 1. Diagram of Overton window, taken from Mackinac Center for Public Policy website.

In this context, it is easy to understand how political tropes become prevalent in social media political messaging. They simplify complex issues, evoke emotional responses, and reinforce ideologies or narratives. Examples of these increasingly pervading tropes in political public discussion in social media are 1980’s Thatcher’s retort*, “You can turn if you want to, the lady is not for turning”, or* 1996’s Blair’s “Education, education, education”, or 2018’s Theresa May’s “*There is no magic money tree”*.

This research introduces "counter-rhetoric" design as a novel method to critically address and challenge ineffective or misleading political rhetoric. By creating and analysing fictional scenarios occurring in the "present", this approach scrutinises the underlying meanings of political tropes and their potential impacts if realised, thereby offering a fresh perspective on evaluating political discourse.

Counter-rhetoric design is linked to critical design thinking and derives from counterfactual design practice, which "offers a narrative in which an event or situation has been changed in the past and a history is developed that establishes an alternative present and depicts an alternative trajectory of socio-technical development" Malpass (2017), and the Alternative Presents speculative practice identified by Auger (2013) p. 12 where "rather than focusing on asking 'what if' of historical events and imagining the effect on here and now, it shifts the emphasis onto artefacts".

Counter-rhetoric design counters failed rhetorical devices by unpacking their original intentions and designing an appropriate system and artefacts that evidence the results of its implementation within a believable scenario.

3. Case Study 1 – Trickle-Down

Thus far, we have outlined the challenges currently affecting rhetorical discourse in contemporary society and have proposed that design can play a role by adding specificity and palpability to political communications. In this section, we outline the first case study that employs a counter-rhetorical design method, focusing on the rhetoric of Trickle-Down economics.

3.1 Trickle-Down Rhetoric

The rhetorical aspect of Trickle-Down economics has a long and varied history. This rhetoric attempts to repackage a classical economic notion into a metaphor that appeals to all. Adam Smith proposed the economic notion in question:

> "[A tax] may obstruct the industry of the people and discourage them from applying to certain branches of business which might give maintenance and employment to great multitudes." (Smith, 1869, p 416)

This disincentivising nature of tax might be true in certain circumstances. However, Smith does not indicate as to the type of taxation. Also, the Industrial Revolution was in its infancy when Smith published his 'Wealth of Nations,' thus, the injustices faced by factory workers were not fully realised. Nor were the tensions between individual profit and taxation as a form of wealth redistribution. Only after the establishment of the wealth fair state in the 20th century did Trickle-Down economics appear in political discourse as a useful way to sell the idea of lower taxes for the higher earners to the public. During his 1981 address from the Oval Office, Ronald Raegan stated:

> "Our aim is to increase our national wealth so all will have more, not just redistribute what we already have which is just a sharing of scarcity. We can begin to reward hard work and risk-taking, by forcing this Government to live within its means." (Address to the Nation on the Economy - February 1981, n.d.)

Trickle-Down was a useful metaphor to justify how lower- or middle-income earners would benefit from low taxation of high earners. Yet the reality and impact of this policy didn't enable wealth distribution or even an increase in GDP; in their 2020 paper 'The Economic Consequences of Major Tax Cuts for the Rich,' London School of Economics senior fellow David Hope states:

> "We find that major tax cuts for the rich push up income inequality… Turning our attention to economic performance… real GDP per capita and the unemployment rate are unaffected by significant reductions in taxes on the rich in both the short and medium term." (Hope & Limberg, 2022)

In fact, the economist Heinz Arndt, in his 1983 paper 'The Trickle-Down Myth', suggests that the usage of the term Trickle-Down was never intended to be applied as a national redistribution tool. Arguing that the post-1945 development economists focused on inequality between countries rather than inequality within a country and assumed that an increase in gross domestic product (GDP) would broadly maintain the same wealth distributions (Arndt, 1983). In this regard, most economists do not take the notion of Trickle-Down economics as a serious economic proposal that enables wealth creation or distribution. Nevertheless, notions of Trickle-Down continue to exist within the political landscape as potent rhetoric. From Ronald Reagan and Margaret Thatcher to, more recently, Liz Truss**.** The notion of Trickle-Down constitutes a powerful political rhetoric but not the economic tool of wealth creation or redistribution that it was claimed to be.

Our project utilises a counter-rhetorical design approach, developing a functional object that enables the implementation of Trickle-Down rhetoric. This allows individuals to contemplate and reflect on the actual effects of applying its foundational ideas.

The project is a speculative design proposal set in 1980s Britain, where a researcher within White Hall proposes the Trickle-Down economic model and prototype devices that turn Trickle-Down from political rhetoric into a function of money.

3.2 Trickle-Down Monetary Design

Our counter-rhetorical fiction starts with Margaret Thatcher's 1983 Conservative conference speech in Blackpool, where she states:

> "One of the great debates of our time is about how much of your money should be spent by the State and how much you should keep to spend on your family. Let us never forget this fundamental truth: the State has no source of money other than money which people earn themselves. If the State wishes to spend more it can do so only by borrowing your savings or by taxing you more. It is no good thinking that someone else will pay—that "someone else" is you… there is only taxpayers' money." (Thatcher, 1983)

Thatcher's speech positioned the state as a taker of people's hard-earned money, but the distinction between rich and poor was not made; thus, the nuances of the arguments for wealth distribution were sidestepped with a straw man argument. However, when pushed during a 1977 interview with William Buckley, she states:

> "I think in societies where there are enormous differences between very great wealth and very great poverty, I would recoil from that… there is therefore something to be said for a certain amount of redistribution." ('What Have We Learned from the Failure of British Socialism?', 1977)

As Thatcher is not against redistribution, the challenge here is to enable some form of wealth distribution within a small state. The economist Friedrich Hayek, who heavily informed Thatcher's thinking, alludes to a potential approach:

> "…It is possible to bring about considerable redistribution under a system of proportional taxation. All that is necessary is to use a substantial part of the revenue to provide services which benefit mainly a particular class or to subsidise it directly." (Hayek, 2020)

'To subsidise it directly' is the key suggestion that informs the idea of placing Trickle-Down into a function of money, but what is a function of money? The 'functions of money' are often found within foundational economic texts, used to define money by its functions: "Money as a Medium of Exchange. Money's primary function is to facilitate trade" (Stiglitz, 2006), "a store of value is an item that people can use to transfer purchasing power from the present to the future" (Mankiw, 2012) and "a unit of account is the yardstick people use to post prices and record debts" (Mankiw, 2012).

Speculative design works have explored the idea of altering the functions of money, but rather than reducing these functions, this project explores the possibility of adding an additional function that bakes wealth distribution to its operation.

Historically, most aspects of money and its functions have evolved over thousands of years and have been largely limited to the characteristics of a given material (commodity currency like gold). Yet, within an electronic fiat currency system, the limitations associated with materials are not present, and money can be designed to incorporate new functions and characteristics. Our counter-rhetorical design proposal takes advantage of this design flexibility that electronic payment systems enable.

3.3 Crafting the Trickle-Down Devices

Thus far, we have outlined the rhetorical proposition that frames our design approach and the monetary theory that could be used to bring the rhetoric into reality. Now, we explore the generative design side of the work.

The speculative design approach used here is like the one outlined by James Auger in 'Crafting the Speculation'. (p.12): "A design speculation requires a bridge to exist between the audience's perception of their world and the fictional element of the concept." Bridging the fictional elements of this work requires reference points from popular culture and technology of the early 1980's. Hence, the industrial design aesthetic was informed by mainstream consumer electronic devices like the Panasonic KX-T1510 answering machine and the late 1970s CR1020 Receiver by Yamaha. Similarly, the technology the devices utilise is from the early 1980's; including the magnetic strip card and reader (IBM invented). And an early version of the early dial-up system 'USENET' created in 1997 by Tom Truscott and Jim Ellis at Duke University ("USENET~," n.d). These historical references act as the bridge to the fictional elements.
The main Trickle-Down device represents a consumer Trickle-Down monitor that a wealthy individual would own; it works by placing a magnetic striped bank card into the slot. When activated it links to their bank account via the phone line and displays the account total and the Trickle-Down rate. The rate of Trickle-Down can be changed depending on the amount held in the account. These rates are set centrally within the government and reflect the current economic priorities of the serving government.

Figure 2. A context shot of the Trickle-Down device.

The Trickle-Down device and system also encourage the natural ‘trickle’ of money through a buffer system, like claiming expenses against taxes within a business. The card owner can spend money in the local economy, which acts as a capacitor. For instance, if £2000 were spent locally, the constant Trickle-Down rate would come from the £2000 rather than the main bank account. This would encourage people to spend in the local economy. If the money is not spent in the economy, then the money will come from the main account.

As the state is reduced, the choice of the destination of the trickle lies with the account owners. They can select lower-level accounts where they want the trickle to fall or a-sign their trickle to any of the open Trickle-Down public receivers positioned by local charities to help those most vulnerable. To bring this aspect of the work into reality, the Trickle-Down public receiver of the money sits alongside the main device. In the context of a gallery space, the audience can experience the process of receiving a small amount of money via the Trickle-Down receiver.

Figure 3. A photo of the trickle-down project displayed at MoneyLab13, organised by NeMe in Cyprus.

Figure 4. A close up of the trickle-down receiver being fed from the consumer device on the right.

During the Moneylab13 conference and exhibition held at NeMe gallery in Cyprus, the audience could play with the cards and device to get a printout (from the smaller device) stipulating how much they had received from the wealthy individual. This brought a level of interaction to the proposal.

4. Case Study 2 – Levelling Up

This section outlines the second case study that employs the counter-rhetorical design method but shifts towards a much nearer time frame. We focus on political rhetoric based on a surprisingly old term: Levelling Up.

4.1 Levelling Up Rhetoric

'Levelling Up' is a term that many politicians today have used to reduce complex issues to a digestible term referencing popular culture. Although it initially sounds rather new concerning political discourse, as our popular imagination recognises it as a gaming term, this belies its long history. One of the first uses on record of 'Levelling Up' is within a political context during the 1860s, in a debate about the Anglican and Catholic churches. During this session, a Lord applied the term in a useful interjection by stating, 'You must arrive at equality either by levelling down or by Levelling Up'. Dr Jack Newman also notes that the phrase was used throughout the 20th century in relation to government spending, being adopted by various governments, including 'The New Labour and the first conservative government of the 21st century. (Newman, n.d.)

Although this longstanding rhetorical term has been utilised during a plethora of different political periods, this project is focused on the 2019 general election, where Boris Johnson won an outright majority on the promise of 'Levelling Up Britain.'

> "This Government is committed to Levelling Up all parts of the United Kingdom – and getting Brexit done will enable us to give new support to people in rural and coastal communities, and for our farming and fishing industries." (2019 Conservative Manifesto, n.d.)

As stated above, 'Levelling Up' was for 'all parts of the United Kingdom' to give 'new support to people.' A 2022 report from the IPPR (Institute for Public Policy Research) states, *"Levelling Up… evokes and reheats many previous agendas but remains less focussed (geographically and thematically) than its predecessors."(Webb, n.d.)* Another report from the Fabián Society comments on the 2 years of inaction

> "›Levelling Up‹ – a vague election slogan from 2019 that has only recently taken form in the government's White Paper and a Bill before parliament." (Raikes, 2022)

Since 2019, living standards have declined, aiding extensive political upheavals. Thus, Levelling Up during the 2019 election constituted a failed and ineffective rhetoric.

4.2 Levelling Up Taxation Design

To have a long-term impact, the aim of 'Levelling Up' an economy would require continuous economic incentives rather than limited or momentary 'funding pots'. Thus, to enable sustained and meaningful Levelling Up in all areas of the UK, systemic economic levers must be utilised to provide continual leverage. Not only this, but these levers need the ability to be fine-tuned between geographical locations and adjusted against a change over time in economic activity. In terms of which possible radical proposal might enable Levelling Up in this systemic way, an idea presented by payments expert David Birch suggests a possible way forward:

> "We should set ourselves up for a world in which there are hundreds, thousands, or even millions of kinds of money. Your phone will show you the price of your latte in London Loot but transfer money in California Cabbage, Apple Apples, and SF Parking Permits." (Birch, 2018)

Numerous currencies might also enable numerous fiscal and monetary policies. Perhaps then, areas with low economic activity would have a currency that would devalue and thus become attractive as an investment, driving growth. However, this market of money might not hold the central control needed to guarantee the Levelling Up agenda promised by the government.

Rather than enacting a dog-eat-dog scenario of currencies, might a dynamic taxation that enables varying tax levels between different areas of the country hold the possibility of encouraging investment in deprived areas? This type of dynamic taxation would only be possible using a digital pound. Could a central bank digital currency enable a more nuanced approach to taxation incentives and disincentives?

4.3 Crafting the Levelling Up Devices

Moving towards the generative side of the Levelling Up project, we employ another counterfactual approach. This scenario proposes a CDBC (central bank digital currency) system that embodies the Levelling Up notion by creating a digital British pound and a variable geographical VAT rate that increases within higher-wealth areas and reduces in lower-wealth areas.

We took a slightly different approach to bridging the gap between the audience and the fiction. Although considerations have been made regarding the aesthetic of the devices to resonate with the context of 10 Downing Street, the believability and communication come mainly from the interactive variable taxation map displayed on the Levelling Up device, which the audience can interact with to help understand the proposal.

The image below depicts the government's Levelling Up device, which enables changes in VAT rates between specific geographical places within the UK. In the scenario, the device is installed within number 10 Downing Street, enabling the government to set and rest the variable tax rates during every new budget.

Figure 5. A close up of the levelling-up device displayed at MoneyLab13, organised by NeMe in Cyprus.

Figure 6. An overview of the display, including the device, fictious address from Boris Johnson and the future wealth disparity maps.

Figure 7. A close-up shot of the wealth disparity map.

Alongside the Level Up device would hang a series of 3d printed wealth disparity maps. Areas of high deprivation are indicated as a peak and low deprivation as a trough. Within the context of this scenario, the 3d printed maps get updated every time the government introduces a new budget, usually once a year. The maps create a lasting and readable reminder of the progress the government policy is making within the UK. Enabling a palpable depiction of wealth distribution within the country over time.

5. Conclusion

This paper has presented the transformative potential of counter-rhetorical design in rethinking how persuasive political arguments are framed and communicated. By employing speculative and critical design methods, we have demonstrated that design can be used to enhance the specificity and tangibility of political discourse. The explorations within the 'Trickle-Down' and 'Level Up' case studies exemplify how such methodologies can critically assess and potentially rectify the fallacies and inefficacies within traditional political rhetoric. This approach fosters a broader conceptual bandwidth for political parties' communications, moving beyond the restrictive confines of Overton's window and engaging more deeply with political processes.

While counter-rhetorical design is a novel mode of political engagement, it faces limitations due to its speculative nature. The hypothetical scenarios it presents may not capture the full complexity of real-world political dynamics and may not be universally applicable or acceptable. The effectiveness of these design interventions in influencing political discourse and public policy remains largely untested and speculative.

Future research should concentrate on empirically testing and measuring the impact of counter-rhetorical design projects, assessing their influence on public opinion and political engagement. This would enhance the efficacy of counter-rhetorical design, consolidating its status as an effective design method for enriching political discourse and democratic engagement.

About the Authors:

Dr Austin Houldsworth PhD, MA (RCA) is an interdisciplinary design researcher with a focus on critical & speculative design. He strives to leverage change through the application of design within unfamiliar disciplines, like creating an 'Intergalactic Space Agency' for the Eden Project or founding the 'Future of Money' design awards.

Dr Carlos Peralta PhD (Cantab) is a multi-award-winning designer, educator, and researcher focusing on design's ideological and societal aspects. Experienced in interdisciplinary collaboration with scientists and design for health, with expertise in product and service design, he uses design to respond to societal challenges.

Acknowledgements: We would like to thank MoneyLab 13 and NeMe in Cyprus for funding and displaying the projects presented in this paper, especially Yiannis Colakides, for making the event happen and for all his support. We also thank Huddersfield University design researcher Dipo Olaosun for his help in ideating the form of the Levelling-up device, the staff and technicians in the workshop at Sheffield Hallam University, who assisted greatly in the production of the components, and Sheffield Hallam University seed funding, which enabled the project to come to fruition.

KEYWORDS | VIDEO GAMES, SPECULATIVE DESIGN, OUTER SPACE EXPLORATION, SCIENCE FICTION, INTERACTIVE MEDIA

ABSTRACT | The narratives around the new frontiers of space exploration promise a future in which humans could become a multi-planetary species that will benefit from the exploitation of extraplanetary resources. Economic opportunities are driving large private investments in the space industry, assuming the role that once was of public institutions in the development of technologies for space exploration and raising concern around legal, ethical and sustainability issues. In this paper video games are interpreted as speculative media that can blend boundaries between the fictional and the actual. Science fiction video games are analyzed as media artifacts that are both representative of neoliberal and colonialist approaches to outer space exploration but, in virtue of their speculative potential, can also promote critical and alternative perspectives. The concepts that allow us to situate games, game worlds, and game mechanics in the context of anticipatory and critical design practices are discussed. It is argued that the acknowledgement and adoption of concepts, ideas, methodologies, approaches, and practices that can resonate both in design and game cultures addresses the need to confront the complexity of contemporary challenges, of which space exploration is a paradigmatic example, from multiple perspectives.

1. Introduction: Trajectories and Narratives of the Space Economy

On February 6, 2018, at 15.45 EST, the Falcon Heavy FH-001 was launched from Launch Complex 29A at Kennedy Space Center in Florida (Uri, 2023). The launch, like the other SpaceX missions, is live streamed, offering the audience an informative yet entertaining overview of all the salient characteristics of the new rocket being tested. In fact, the Falcon Heavy is one of the most powerful super heavy-lift launch vehicles ever built, capable of delivering nearly 64 metric tons to low Earth orbit (SpaceX, 2021). SpaceX's Falcon Heavy and the Starship, which is currently under development, address the growing market demand for reliable and cost-effective launchers capable of carrying materials, satellites, and humans to orbit. It has been estimated that the satellite payload market size will reach 24.51 billion USD by 2029 (Satellite Payload Market Size Report, 2024), demonstrating private interest in the commercial opportunities of the space economy. During the streaming, every stage of the startup sequence that is successfully completed is cheered by the crowd of SpaceX engineers attending the launch from the mission control room. The broadcasting conveys the excitement and the tension of the moment. During the minutes leading to the launch, the mission profile is presented in detail by representatives of the company's departments. Finally, when the countdown reaches zero, the Falcon Heavy rocket successfully lifts off from the launch pad with a deep, powerful roar. The crowd cheers and shouts loudly with joy. Cameras alternate views from the ground and from the rocket itself, offering dramatic perspectives of the rocket lifting from Earth. After reaching an altitude of 60 km, 2 minutes, and 38 seconds into the flight, the side busters shut down and separated from the main rocket. They will successfully perform a choreographic synchronous vertical landing on Landing Zone 1 and 2 in the famous Cape Canaveral Space Force Station. A few seconds later, the central core engine is turned off and dethatched from the upper stage of the rocket that contains the payload. Cheers of celebration. The onboard camera shows the upper stage's engine glowing while the Earth profile moves in the background. After 3 minutes and 45 seconds of flight, the crowd's cheering and the mission control audio is suddenly drowned out by the sound of an electric guitar and by the lyrics of David Bowie's song *Life of Mars*. The camera is now framing Starman, an astronaut mannequin comfortably and boldly sitting at the wheel of Elon Musk's own red Tesla Roadster mounted on a support system inside of the upper stage fairing, the protective shell that contains the material to be shipped to orbit. The fairing is finally deployed, revealing a spectacular view of Starman riding his supercar into the universe with the Earth in the background.

In the described mission, Musk's Tesla has been used as a dummy payload, a nonfunctional mass that simulates the loading capacity of a spacecraft during test launches. Dummy payloads are used to evaluate the spacecraft's behavior when loaded with material's, equipment's, and crew's weight. Dummy payloads are generally used during test flights since the high chance of failures. Although any object with comparable size and weight would have effectively served as a dummy payload, using a Tesla Roadster offered an unprecedented marketing opportunity for both Elon Musk's companies, SpaceX and Tesla.

The new frontiers of space exploration promise a future in which humans could become a multi-planetary species that will benefit from exploiting extraplanetary resources. This vision and the economic opportunities it prospects are driving large private capital investments in the space industry, assuming the role that once was of national institutions in the development of technologies for space exploration. The growth of private capital flows in such a strategic industry is raising concerns around legal, ethical, and sustainability issues (Iliopoulos & Esteban, 2020). The dramatization of outer space operations offers a spectacle of private companies' technological achievements underplaying the complex issues of power and control that derive from the private ownership of such technologies. Moreover, such a spectacle contributes to the construction of the contemporary narrative about human space endeavor that shows to gather impulse from neo-colonialism modes of approaching space exploration (Mitchell et al., 2020). A narrative that exposes the utilitarian and neoliberal perspective of private interest in developing human access to outer space.

Together with the cinematic commercials of private companies, contemporary media artifacts concur to the construction of the space culture narrative, both dramatizing the real events of past and contemporary

space exploration and using fiction to project the future speculative frontiers of space travel. Considering works of fiction, in fact, the conquest of space colonies, the visions of space tourism, and the story of intergalactic wars for resources and territory control are widely depicted in numerous sci-fi novels, movies, and video games. Science fiction novels have largely contributed to inspire scientists and engineers in the development of new technologies. The influence of science fiction novels on real-world space artifacts has been discussed in the analysis of the design for future space habitats (Ceylan, 2018, 2022), new technologies and interfaces (Figueiredo et al., 2015; Kendrick, 2002), and new forms of outer space commercial travels (Ceuterick & Johnson, 2019).

In this context, however, alternative and diverse ways of approaching space exploration are being discussed to challenge the dominant spaceflight culture and narrative to acknowledge diverse and underrepresented perspectives (Schwartz et al., 2023). Fictional representations of space exploration, and science fiction in particular, play a significant role in the diffusion of space culture and shaping people's opinions on emerging technologies. Isaac Asimov, considered one of the seminal authors of the genre, considers science fiction novels a form of response to the transformations happening in technology and society (Asimov, 1982). From a critical design point of view, the analysis of future-oriented narrative artifacts offers the opportunity to reflect on emerging attitudes toward technological and cultural transformations. In particular, examining contemporary science fiction media, it can be observed which political and economic values are emerging as drivers that motivate the future human presence outside Earth's boundaries. This paper discusses how video games, and science fiction video games in particular, can be understood as interactive forms of design fiction that speculate on the future of outer space exploration. It is argued that, despite the dominance of a neo-colonialist and exploitative rhetoric, video games can advocate for a critical perspective on the future of human space presence in outer space that is driven by values alternative to that of neoliberal capitalism. Play is a form of expression of ideas and values, a creative form of production, and not a mere form of consumption (Sicart, 2014). A critical perspective towards future scenarios can be developed through the experience of play, and video games solicit such an attitude through the distinctive qualities of the medium that will be discussed in the next paragraphs.

1.1 Methodology

The introduction of this paper reports a specific SpaceX's mission streaming as a representative example of the current dominant narrative on human endeavor for outer space exploration. Being a highly experimental field, it requires powerful and evocative depictions to drive investors' interest to the space economy. Such representations not only serve this purpose but also shape the dominant narrative on space exploration in Western countries. This paper aims to analyze science fiction video games as media artifacts that are both representative of neoliberal and colonialist approaches to outer space exploration but, in virtue of their speculative potential, can also promote critical and alternative perspectives. For doing so, literature on games and play has been reviewed to bring out the concepts that allows to situate games, game worlds, and game mechanics in the context of anticipatory and critical design practices. The identified defining ideas of speculative design are confronted with related concepts specific to the medium of video games. The discussion is presented in paragraph 2. It constitutes the theoretical premise that allows to observe science fiction video games as materialization of actual and future perspectives on outer space exploration, which is discussed in paragraph 3. Paragraph 4 uses two case studies to exemplify the ways video game can address science fiction scenarios without adopting narrative and visual clichés. The two games have been chosen as case studies to exemplify how both commercial and non-commercial games can offer alternative perspectives on the discussed topic of outer space exploration. Moreover, unlike the other games mentioned which are products developed by established game companies, the selected games are representative of two bottom-up design processes: a workshop activity and a thesis project that developed in a successful commercial product.

2. Video Games as Speculative Media

In contemporary technocultural society, the specificities of video games bear an "aesthetic potential which allows for speculation over the very structure of knowledge and contemporary technology" (Luersen & Paula, 2023). In this paper, video games are interpreted as speculative media that can blend boundaries between the fictional and the actual. Several scholars have addressed the multiple connections between video games and speculative practices, discussing how worldbuilding and diegetic elements intertwine with the mechanics of play themselves and the effect on player experience and critical reaction.

Games have reflected the cultural and ideological values of society since ancient times. Video games represent the interaction and the conflicts of social and technological transformations. They are both cultural objects (Dovey & Kennedy, 2006; Schrank, 2014), materialization of the commodity from (Celaschi, 2000) in the contemporary market exchange system (Jagoda, 2020), and products of a complex industrial system (Dyer-Witheford & De Peuter, 2009; Woodcock, 2019). Through the practice of appropriation and re-functionalization, ludic artifacts can suggest and invite critical reflections on social, ethical, and political issues. The manipulation of the game structures and affordances in avant-garde games (Schrank, 2014), the adoption of "radical" (Flanagan, 2009/2013) and critical (Grace, 2014) approaches to game design, and the appropriation and re-functionalization of the medium, such as in the case of machinima and game mods (Joseph DeLappe, 2018), are some of the methodologies and practices that have been adopted to address political and social issues through games.

As a medium, it can be argued that video games can be considered an interactive form of design fiction. Despite being commercial products (whereas design fiction and speculative artifacts generally are not), games are inherently speculative. The in-game decisions players are continuously faced with and the layering of slight interactions that add up during the gaming experience force a constant speculation on the possible outcomes of one's decision (Kunzelman, 2022). With a particular focus on science fiction games, Kunzelman describes the "mechanics of speculation" as the "ways that games specifically ask us to engage in speculative practices while playing them" (Kunzelman, 2022, p. 22). As presented by Kunzelman, those mechanics are specific to the medium and can produce several effects on the players, from Brechtian estrangement to the stage of the differences between the actual and the fictional world, between one ideology or the other. In design fiction, the narrative is functional to the representation, in the form of prototypes, of the transformed or alternate world (Sterling, 2013). In game worlds, mechanics can be considered narrative devices that produce real-time events and responses to player action (Dubbelman, 2016). Game mechanics determine the limits of the action and the type of affordances accessible in the game world but also activate mechanics of speculation within it.

Compared to linear media, games are defined by rules within a system in which players engage (Salen & Zimmerman, 2004). Such a system constitutes a possibility space that is discovered and interpreted by players through their performance (Squire, 2008). The frame of rules and objectives that regulates the game world combine with the possibility and the indeterminacy of play, characterizing video games as experimental artifacts (Jagoda, 2020). As argued by Jagoda, games are experimental both in formalist terms for their capability to model alternative forms of reality and for offering players a possibility space (Squire, 2008) where the uncertainty of play can encourage the emergence of difference and unpredicted outcomes. Games offer a space for experiencing an alternative vision of the world and exploring the dynamics of alternative control and power structures. In their book on fictional games, Gualeni and Fassone (2022) explore the role of fictional ludic artifacts that only exist in narrative worlds. Fictional games lack complete game rules or can function only through technological or magical elements that make them impossible to play in the real world. It can be argued that fictional games act as forms of diegetic prototypes (Kirby, 2010), that are contextualized as real functioning (playable) artifacts within the narrative. They emerge as the materialization of social and cultural values or, by contrast, as ludic forms of reaction to the established dominant powers. In fact, fictional games can act as transformative tools, questioning the socio-political environment depicted in the fictional world and becoming utopian tools. They can transform, through the indeterminacy of game dynamics, dystopian narratives into acts of

critique (Gualeni, 2021). Even within the grim and undesirable characters of a dystopian narrative, critical dystopias open a space of contestation and propose the hope of a positive alternative, if not within the narrative itself, at least outside of it (Baccolini & Moylan, 2003).

Besides its capability to address social conflicts and issues through the materiality of design, design fiction is a design practice that can be adapted to support the development of new real-world technologies. The diegetic prototypes of design fiction conceptualize and enable reasoning about the impact and possible applications of new technologies (Bleecker, 2009). The artifacts of science fiction prototyping (Johnson, 2011) represent the design concept of the things that one day will be possible to build. Games artifacts materialize such prototypes situating them both as functional and interactive means, and as technocultural expression of the fictional world.

Effective speculative design needs to build "perceptual bridges" between the observer's reality and the speculative future (Auger, 2013). Auger suggests that such perceptual bridges can be inspired by different fields, such as psychology and comedy, that offer insights into the way the human mind works. In games, these perceptual bridges are constantly built through the complex combination of aesthetic, kinesthetic, and sensorial experiences of game feel (Swink, 2009). The sensation deriving from the feeling of directly and precisely controlling the avatar, from the physical interaction with the simulated world, and from the effects that polish and enhance the interactions, act on players' nonconscious cognition as affective experiences (Jagoda, 2020, p. 116), and constitute the medium-specific perceptual bridges to the speculation.

The concepts that have been briefly discussed in this paragraph constitute a reference framework that situates games as a form of speculative media. The next paragraph introduces science fiction games as a genre that is particularly representative of the speculative qualities of video games and problematizes the dominance of colonialist themes that, it is argued, are representative of contemporary space endeavors.

3. Speculative Scenario of Outer Space Exploration in Sci-Fi Video Games

Science fiction and games have been sharing themes and visual iconography since the origin of the video game medium. From *Spacewar!* (Russell, 1962) and *Space Invaders* (Taito, 1978), to the *Halo* series (343 Industries et al., 2001-2021) and the recently published *Starfield* (Bethesda Game Studios, 2023), games have represented science fiction and space exploration narratives with increasing visual accuracy and technical sophistication. Science fiction games have developed in a wide variety of subgenres, among which space simulators are one the most representative because of the game mechanics it has introduced. Space simulations can be subdivided into two main categories of space combat simulation and space exploration simulations (Tringham, 2013, p. 413). As reported by Tringham, *Star Raiders* (Atari, 1979) can be considered one of the first examples of the space combat form that introduced the fundamental features, such as the presence of strategic mechanics and resource management systems, that characterize the genre still today. Regarding exploration games, *Elite* (Barben & Bell, 1984) is considered the first prototypical example of space exploration simulation presented as an open-ended large real-time 3D explorable universe where to collect, trade and fight for resources. The idea of procedurally generated game words introduced by *Elite* has developed in numerous game genres. A recent example of a science fiction game that largely uses procedural generation is *No Man's Sky* (Hello Games,2016) whose explorable universe is constituted of 18 quintillion planets, each characterized by a unique geology, flora, and fauna.

The peculiarity of science fiction video games, compared to other game genres and other mediums, has been observed in their capability to "convey a more active sense of futurity" (Frelik, 2014, p. 230). Moreover, as a medium, games reach a vast and diverse audience, making the ideas and concepts of science fiction more accessible. Frelik identifies four intersections between the medium of video games and the mode of science fiction. Video games "as narratives of space […]", "as integral elements of distributed narratives spanning multiple media and forms", "as instanced of visual science fictions invested in the pictorial portrayal of futurity", "as performative simulation, conveying a sense of malleability of the future" (Frelik, 2014, p. 230).

In discussing the argument of this paper, the spatiality of science fiction video games is particularly relevant. As suggested by Frelik, in science fiction games, spatiality emerges in two specific aspects. The first one is worldbuilding. Through the construction of coherent and complex fictional scenarios, players are confronted with visions of alien planets, extraterrestrial settlements, and advanced technologies. Compared to movies, which also provide strong and descriptive visual cues, games enable players to freely navigate such fictional universes, providing an "affective experience of the genre's sense of alterity" (Frelik, 2014, p. 231). Speculative practices heavily rely on worldbuilding and environmental narratives. Speculative cinematic narratives, such as *Planet City* (Young, 2021), guide observers through the architecture, the rituals, the technologies, and the identities of fictional future scenarios in which humanity addresses the environmental crisis in a radical way. In *Plane City* speculation, humanity gathers in a hyper-densely populated city, leaving the rest of the planet to nature. The project, in addition to a cinematic representation, uses essays and costumes to explore the technical, environmental, social, and cultural implications of such a scenario. The video game series *Mass Effects* (BioWare, 2007, 2010, 2012) offers a parallel to a similar speculation. In the game, the *Citadel* is a hyper-dense galactic settlement where humans and alien species coexist under the government of the *Citadel Council*. The massive galactic infrastructure resembles that of an O'Niell Cylinder, a conceptual outer space infrastructure proposed by Gerard K. O'Neill in the 1970s (O'Neill, 1977/2000) that generates artificial gravity through centrifugal acceleration. Compared to O'Niell design, the lateral surface structure of the *Citadel* is not continuous, but it is constituted by five 43.6 kilometers of arms (the Wards) that extend from a central pentagram-shaped ring with a diameter of 7.2 kilometers. The *Citadel* portrays the organizational structure of the social system that relies upon advanced technology. In the same way, *Plane City* suggests a critical reflection of how the political and social structure could operate in combination with technological infrastructures in a complex superorganism. The spatiality of games allows the exploration of such natural and artificial speculative environments, soliciting players to explore the architecture, the technologies, and the affordances offered by such artifacts and the dynamics of different social structures.

Another spatial-related mode, Frelik suggests, is represented by the narratives of conquer and exploitation of extraterrestrial worlds and living beings. Such trait, as already discussed, is recursive in both fictional media, but also suggested by the commercial narratives of the space industry. With few exceptions, most science fiction video games propose imperialistic narratives and forms of exploitation and control (Frelik, 2014). The main themes revolve around spaceship flight and combat, military strategy, survival of dangerous and dreadful extraplanetary environments, and new worlds colonization (Majsova, 2014). Such narratives have been present in science fiction video games since the origin of the medium, which roughly coincides with the years of the Space Race and the Cold War between the United States of America and the Soviet Union. The competition between the two blocks drove large investments in technological innovation for developing military and defense applications. During this period, the emerging video game industry offered a space to programmers where to develop game technologies without military implications (Izushi & Aoyama, 2006). Although the entertainment, technical, and artistic value of this production is acknowledged, it is argued that the abundance of such themes is representative of the utilitarian, exploitative, and neo-colonialist attitudes that have animated, and still animate, past and contemporary perspectives on outer space exploration. If during the Space Race period, science fiction video games' themes reflected the political and military tension between nations, today's neoliberal values that nurture private companies' efforts to access outer space are mirrored in the science fiction game mechanics of resource accumulation, management, and crafting. For Roberts, understanding something as science fiction depends on the moment and the context of reception (Kunzelman, 2022, p. 6; Roberts, 2005/2016). As an example, *Blade Runner* (Scott, 1982) movie portrays climate crisis as an energetic, continuous anthropogenic process driven by capitalist interests that destroy the environment and voraciously consume resources. In *Blade Runner 2049 (Villeneuve, 2017),* the world's resources have ended and the world has been consumed. It can be argued that today, in light of a different perception of climate issues influenced both by the ecological debate and by the witnessing of the effects of climate change, *2049* climate dystopia resonates more with contemporary concerns about climate crisis compared to 1982's movie. In this sense, today's science fiction video games solicit a strong connection with the future of outer space exploration prospected by contemporary narratives of private companies.

4. Escaping Science Fiction Speculation Cliché's Orbit

It has been argued that the adoption of strong dystopian visual clichés in movies (and games) may represent a limit of the medium's capability to invite a critical reflection from the viewers, since they can passively rely on the genre's canonic categories to shape their interpretation (Dunne & Raby, 2013, p. 75). The effort that is required for the reader of science fiction novels is to visualize the story in a process that moves from one word to the other. The subjunctive level of science fiction, being the possibility that certain events could or could not happen, requires a progressive correction process of the visualization that happens in the readers' mind that is coherent with their understanding of the physically explainable universe (Delany, 2009). In visual media, viewers don't need to make a visualization effort. Yet, the critical understanding of the artifacts within the fictional world and their relations with the speculative environment are still there to be made. Visual clichés narrow down the speculation process toward beaten tracks. Hence, when considering science fiction video games as speculative media, original critical and speculative enquires can arise from game worlds that propose alternative narratives and different perspectives that avoid recurring genre clichés. Games can evade stereotypes and clichés by radicalizing the boundaries of the speculation. Still maintaining the "perceptual bridges" with the player's world, visual references can be metaphorized by the worldbuilding and articulate speculation on a more abstract but fundamental level. In science fiction narratives, readers, viewers, and players are constantly invited to make parallels with their own reality. Both scenarist and narrative cliché weaken the speculative potential of science fiction since not much effort is required to situate one's own values within the alternate reality of the fictional world.

Two examples have been chosen to discuss how extreme or radical speculative scenarios can be vehicles to bring different values into the space exploration discourse and, therefore, to broaden the boundaries of inclusion. *He Ao Hou: A New World*[1] (Na Anae Mahiki Collective, 2017) is a game developed during the 2017 SKINS 5.0 workshop as part of the activities promoted by the *Initiative for Indigenous Futures*[2]. During the three-week workshop, Hawaiian indigenous people were given tools and knowledge to develop a video game on the topic of indigenous narratives in a setting of indigenous futurism (Dillon, 2012). As discussed by one of the workshop coordinators Rilla Khaled (Kahled, 2022), the game addresses questions related to the decolonialization of space exploration. The developed game is a point-and-click adventure game in which players explore different worlds inspired by *Mo'olelo*, the traditional Native Hawaiian stories. The progress in the game is achieved through the knowledge of *Mo'olelo* and through the *Aloha 'Āina*, the ecological principle of spiritual, cultural, and social Native Hawaiian identity. In the game, the kukui nut, a symbol of knowledge for Hawaiian Indigenous people, is used as an artifact that allows interactions with the world. The game developed from a radical perspective in which economic or political reasons do not foster space exploration but is a discovery and growth process in accord with the foundational values of the indigenous population. Despite not speculating on practical technologies and solutions to align the contemporary attitudes of space economy to the game proposed values, it points out how underrepresented and unacknowledged such perspectives are. In this act of re-actualization, designers intervein as mediators of knowledge and sensibilities in a co-design process of materialization of these values in game environments, mechanics, and narratives. Moreover, this project stands out as a form of reaction against the Western politics of settler colonialism that are inherent to Indigenous territory occupation for the construction of space research facilities (Sammler & Lynch, 2021; Smiles, 2020). Mauna Kea is a quiescent volcano in the Hawaiian archipelago and, in virtue of the characteristics of the site, is the location of a dozen observatories. Since 2014, local communities have started protests and legal battles against the construction of the Thirty Meter Telescope (TMT) since Mount Kae is the most sacred mountain to Hawaiian people. With the growing interest of private companies in the space economy, there is a growing risk for underrepresented and indigenous communities to undergo exploitative politics. From this case study, it emerges the importance to include marginalized perspectives in the design of speculative artifacts in order to disrupt the hegemonic perspectives that are often represented in the mainstream visions of the future.

[1] The game is freely accessible at: https://skins.abtec.org/skins5.0/?page_id=1689.

[2] https://indigenousfutures.net.

Another game that can considered an example of science fiction that avoids visual clichés is *Outer Wilds* (Mobius Digital, 2019). *Outer Wilds* is a successful commercial video game that proposes an exploration adventure of a fantastic solar system. The game, developed from Alex Beachum's Master Thesis project at USC Interactive Media & Games Division (Beachum, 2013), combines elements of science fiction and fictional archaeology. The gameplay is based on a 22-minute loop that recursively brings the players to their planet of origin. The game progression is not based on the usual mechanics of skills' acquisition or mission achievements. The element that drives progression in the game is the acquisition of information that players need to elaborate to understand the events happening the game universe and how to proceed in the exploration. It has been argued that in *Outer Wilds* "the experience of learning and knowing proceeds from an obstinate tension toward the unknown" that constitutes a game mechanic that "values curiosity and exploration over achievements" (Luersen & Paula, 2023, p. 17). As well as the previous example, the artifacts players can use are probes to investigate the world and gather clues that contribute to form speculation about the game universe. These artifacts do not propose self-reflective speculation on technology but depict technology as a means to access information and develop knowledge. As discussed by Luersen and Paula, in *Outer Wilds,* the devices players can use to explore the solar system (such as the signal scope that detects acoustic signals, the probe that allows the survey of inaccessible areas, and the translation tool that translates the inscriptions of the extinct alien civilization) establish with the data they produce and the player a meaningful relationship that drives the experience of discovery (Luersen & Paula, 2023). Reflecting such critical observation on our actual reality, the instruments that have been sent to orbit over the years have produced knowledge about the universe and the Earth. Military technologies and services based on space infrastructure have become accessible to a greater number of people. However, contemporary conflicts, social and climate challenges make orbital infrastructures and satellite data a strategic and critical asset. In this context, the contribution of critical design is to balance the economic value of space operations with the social one adopting speculative artifact as means of representation, analysis, and critique. Critical design needs to advocate for a just and responsible distribution of the positive impacts of the space endeavor, broadening the discussion and reflecting on the ways designers can contribute to this process.

If the dominant narratives of the majority of science fiction video game impose a top-down perspective of the futures, countergaming (Galloway, 2006/2022) practices propose alternative ways of engaging with such scenarios, turning them into platforms for divergent speculation. For Galloways, countergaming is a form of critical engagement with the game medium that questions the hegemonic practices of the game industry. Game mods are a form of countergaming. Modifying the game code to alter the gameplay mechanics, the control system, and the visual representation of the 3D environment, is a form of appropriation and re-functionalization that establishes a negotiation between the imposed narrative of the game world and the players' sensibilities. Another way to open up and subvert confined game narratives is through the making of machinima (Berkeley, 2006). Machinima can be seen as another form of countergaming. Machinima are linear media such as short movies, video essays or feature-length films that are produced within the game environment and recorded through the game rendering engine. Authors of machinima often remediate the game system into a tool for telling stories unrelated with the original game narrative. Some machinima authors even intervein on the game code to introduce new 3D models, custom visual effects, or additional camera viewpoints. Although games propose their own representation of fictional and speculative futures through worldbuilding, narrative and gameplay, an approach that leverages critical engagement and countergaming practices suggests that video games can be adopted as speculative platforms in anticipatory design practices.

5. Conclusions

In this paper, it has been argued that video games, and science fiction video games in particular, can be understood as speculative artifacts that can propose alternative perspectives on outer space exploration, which is currently dominated by neoliberal and neocolonialist ideals. It has been discussed how both private companies' self-narration and science fiction media concur to represent future scenarios in which human presence in outer space is primary driven by exploitative interests and implemented through forms

of neocolonialism. However, it is argued that both commercial and non-commercial games can become platforms for developing critical reflections and promoting forms of reaction to the values and means that drive contemporary outer space exploration. Such critical artifacts, rather than suggesting technical solutions or practical approaches, fictionalize novel perspectives emerging from the alternative ideals that aim to nurture the space endeavor. It emerges the need to involve marginalized and underrepresented communities in the co-design of speculative artifacts, which come to be empowering tools that challenge the hegemonic perspectives on future technologies and their use. For their capability to reach and engage with a vast audience, video games can be adopted as speculative platforms that contribute to including more people, a wider range of sensibilities and more diverse identities in the public discourse on space exploration politics. The commercial narratives proposed by private space operators, based on the exploitative premises of the space economy, restrict the boundaries of inclusion towards those who don't share such a vision. Understanding video games as speculative media enables designers to adopt game design approaches to explore new methods for speculative enquiries and to engage with games as critical artifacts that can reflect and develop in design practice. The acknowledgment of concepts, ideas, methodologies, approaches, and practices that can resonate both in design and game cultures addresses the need to confront the complexity of contemporaneity from multiple perspectives. The adoption of video games as tools and methods for broadening the discussion on such relevant topics is synergic with other co-design practices. In fact, the inclusion of underrepresented communities in the co-design of speculative games, as the *He Ao Hou* case study demonstrates, allows to escape science-fiction clichés promoting the development of divergent speculative scenarios. Forms of countergaming, re-mediation, re-functionalization, and appropriation allow designers and non-designer to critically engage with the game worlds, promoting bottom-up critical and creative processes. Future development of the arguments presented in this paper will investigate how design can act as a mediator in developing a promising research field at the intersection between game design and cultures, playful design, speculative and anticipatory design practices, and critical theory.

About the Author:

Alberto Calleo is a Building Engineer-Architect, PhD Student at the Department of Architecture of the University of Bologna. His research interests concern the intersections between digital media practices and design cultures. He conducts research in the field of speculative design and anticipation using video games and interactive media. His research interests include creative applications of 3d modeling, photogrammetry, aero-photogrammetry, and laser scanning. He is active in applied research projects with various national companies.

Acknowledgements: I would like to thank the reviewers for their insightful comments and the colleagues of the Advanced Design Unit of the University of Bologna for their support.

KEYWORDS | SPECULATIVE DESIGN, COMMUNICATION DESIGN, CLIMATE CHANGE, PROTOTYPING, EDUCATION

ABSTRACT | The paper explores the implementation of an anti-disciplinary approach within a Communication Design Studio at Politecnico di Milano, focusing on teaching visual identity and experience design through a speculative design framework. Students are encouraged to engage in problem-seeking and problem-finding practices, fostering the development of concepts and scenarios without predetermined functions.

The studio's main outputs are communication design ecosystems manifested through visual identities, experiences, and Communicative Machines prototypes. These artefacts were showcased in an open event/exhibition, inviting external feedback. Anthropogenic Narratives, starting from the assumption of proposing non-human perspectives (e.g., the ones of rocks, sun, moon, or ice), aim to provoke and activate reflections on the relationship between humans and nature. Each subject is treated as a fictional organisation, which communicates through all the necessary elements of a fictional brand and related touchpoints, unfolding futuristic scenarios while involving the human/user in interactive experiences essential to understanding the narratives. The results come from an experimental educational path based on the risk of trying new solutions and techniques and verifying them on a real scale. Design speculations that are not meant to give answers and certainties aim to imagine new questions and reflect on contemporary and future times. A learning path that intends to go beyond the centrality of téchne to encourage the wielding of knowledge.

1. Introduction: Climate Change, the Role of Design and Critical Stances

The relationship between humans and nature needs to be changed, mainly due to the upheavals triggered by human activities within the last three centuries. The topic of climate change causes discussions and debates. However, most public opinion appears to stand still in front of such modifications rather than becoming aware of their role. Discussing these issues, especially in the context of education, is crucial.

Humanity is facing the most complex challenge it has ever experienced. If our Earth has passed through extreme events, such as the Ice Ages, the crisis the world has faced in recent years, although equally severe and urgent, is very different. In this case, it is possible to identify who is at fault, the ones responsible for the dangerous conditions that human beings and all the other ecosystems are experiencing. Earth is over 4,5 billion years old, while humanity has existed for just 200.000 years. Less than 0.04% of Earth's existence was enough to radically change the environment on which all species depend. The Earth has always experienced change, but the peculiarity of this crisis is the increasing rhythm at which these changes are happening. Indeed, climate change is getting worse year after year, and though there is awareness and discussion on the topic, nothing seems enough to provoke serious action.

Though the data related to the possible risks is clear and easily accessible, the changes in people's daily lives are still not enough. According to a report published by the Pew Research Center (Funk & Kennedy, 2016), although most Americans express to care about the environment, only a much smaller percentage declare to "always try to live in a way that helps the environment." Three-quarters declare themselves as particularly concerned with helping the environment in their daily lives. Nevertheless, only two in ten (20%) describe themselves as people who strive to live "sustainably always." These are cases of cognitive dissonance, a psychological phenomenon that occurs when a person holds contradictory values or attitudes and their actions conflict with their beliefs. It often leads to rationalising people's behaviour by minimising the importance of actions or blaming others for the problem (Jonas et al., 2014). Another bias is the so-called diffusion of responsibility, a process underlying the bystander effect that refers to the fact that as the number of people participating in the problem increases, the personal responsibility that an individual feels decreases (Blagg, 2023).

As Mitrović (2018) highlights, "Design, as the driver of modernism, also had its role in the establishment of the so-called 'Anthropocene' (or 'Capitalocene'), which more than ever in human history opens possibilities for extreme catastrophic scenarios that are about to take place shortly." The term 'Anthropocene' refers to the impact of collective human activity on biological, physical, and chemical processes at and around the Earth's surface ("Anthropocene", 2023). Design has always been a driver for innovation. However, the kind of solutions that have been developed were, most of the time, new tools and products, a race to go beyond the old and substitute with something brand new. When humans understood the consequences of this massive production, they started to shift the design processes to the methodology. Mitrović adds:

> "The idea that design thinking as a method could be used for resolving problems in business or everyday life has conquered the neo-liberal world. Through concepts and business models offering methods and tools for 'designing one's own life' [...], this business philosophy tends to transform into a worldview." (Mitrović, 2018)

It is clear indeed that design has played an uncritical supporting role to industry (Auger, 2023, pp. 65–76), determining the situation we are living in nowadays. "Most of the time, without reflecting on the implications of […] [his] actions" (Mitrović, 2023, p. 31).

As affirmed by Auger (2016), “contemporary design is a fundamental part of a postmodern socioeconomic system, inextricably linked to entrenched notions of progress, the manipulation of desire and conspicuous consumption.” Following and contributing to the dogma of progress as a way to achieve a better life, design has paradoxically been left behind by its modernist promises and principles (Colomina & Wigley, 2016), showing the limits of its deterministic spirit. In this condition, it becomes necessary to re-think new roles for design itself (Dunne & Raby, 2013, p. 12).

The rise of user-centred or human-centred approaches testifies to how the anthropocentric perspective has dominated all the aspects of research and production in the design fields (Sznel, 2020; Borthwick et al., 2022).

Norman (2023), the father of user experience design, in his recent book, “Design for a Better World”, states that designers should embrace the need to transition from human-centred design to an eco-systemic approach to humanity. This diverse mindset could help them to have a more comprehensive understanding of their responsibility to the people they design for.
The underlying belief to all these problems, as we already affirmed above, is anthropocentrism, the conviction that a particular species, Homo Sapiens, has some kind of privileged relationship with objects in the world (Caffo, 2017). It is a metaphysical system that considers all other beings as tools to serve humans’ interests (Rao, 2021).

These premises were the starting point from which the 2022/2023 edition of the Final Synthesis Communication Design Studio (Section C1), third year, Bachelor in Communication Design at Politecnico di Milano, took place. The belief is that sustainability-related changes and our connection with the planet require profound critical reflections and a significant shift in perspective, moving away from a purely human-centred view. It is a shift that entails expanding our outlook to consider the perspectives of all creatures involved in our ecosystems, even those typically overlooked, and granting them a voice in the discussion. As a field of practice, design disciplines have “the potential to detect, mediate and generate new relations and to encourage radical imagination” (Mitrović, 2023, p. 35).

Speculative design revealed itself as the perfect framework to do so. It offers the opportunity for an anti-disciplinary approach, using traditional and established design tools and methods to face “wicked problems” (Dunne & Raby, 2013, p. 2): challenges regarding the existence of no immediate or easy resolution, opening discussion in a disruptive way.

2. The Design Studio: Designing Speculations

Through imagination and a radical approach, speculative practice inspires thinking, raises awareness, examines, provokes actions, opens discussions, and provides alternatives needed in today’s world (Mitrović, 2019). With critical thinking, the design of objects generating a story or through the stories embodied in artefacts, speculative design attempts to anticipate the future and, at the same time, helps us re-think the world of today. In that sense, the practices related to Speculative Design reveal this potential and how successful it is as “an experimental environment to test different hypotheses about our lives in the future” (Mitrović, 2023, p. 35).

The statements mentioned above consistently convey the idea that design, specifically communication design, far from being a mere problem-solving framework and a commercial-oriented practice, can also be a tool for exploration and questioning to investigate and face the uncertainty of our contemporaneity. These insights form a fitting foundation for undergraduate teaching, which we will describe and discuss in the following paragraphs. This level of education seeks to equip students with technical skills and a spectrum of soft skills essential for professional practice. But with a robust critical consciousness.
The education path’s main goal, integrating research into and through learning, was to imagine and design possible, if not probable (excluding the preferable) futures, conducting and stimulating intentionally critical reflections on the present.

The main outputs to develop were communication design ecosystems within an anti-disciplinary approach, adopting a speculative design framework. Some developed main elements are visual identities, experiences, and prototypes (called Communicative Machines and at a 1:1 scale) to verify with an external audience.

Another goal of the Communication Design Studio, in terms of critical stances, was to make designers question their ethical role. To link the needs of a world in crisis, asking for action, awareness, and responsibility, to the one of education, the perfect place to stimulate these processes, experimenting with traditional methods and approaches to face severe and unresolvable problems.

In an educational context, adopting such an approach (e.g. Speculative Design, Critical Design, or Design Fiction) offers educators a means to help students develop practical design skills and critical thinking abilities (Helgason, 2020). As an educational tool, it broadens students' perspectives, encouraging them to "think more creatively and critically about the role of design in our shared futures" (Auger, Hanna & Mitrović, 2021, p. 21) and apply design principles across diverse contexts and project types. Most design education programs still adhere to "the modernist rational and functional understanding of design as a problem-solving discipline" (Grakalić, 2020). However, it is increasingly essential for designers to cultivate a capacity for "reflective practice" and learn to function as "researchers within the practice context" (Schön, 1983, p. 68), moving beyond mere problem-solving. It wasn't just a technique or a methodology taught to the students, but the development of a different attitude, the desire for more awareness, that gave birth to projects that demonstrated understanding and judgmental criticism towards something so delicate yet fundamental as the subject of climate change is.

The brief, starting from the assumption of proposing non-human perspectives (e.g., rocks, moon, sun, ice), aimed to provoke and activate reflections on the relationship between humans and nature. As affirmed by Rao (2021), speculative design allows expanding thinking to consider the perspectives and viewpoints of the "other" that lies beyond human experience and perception. All objects, living and non-living entities, have the same degree of being in the world. Through this reversal, the invitation expressed by the brief was precisely to imagine, discuss and speculate how nature could experience climate change.

Each subject was treated as a fictional organisation, which communicates through all the necessary elements of a fictional brand and related touchpoints, unfolding futuristic scenarios while involving the human/user in interactive experiences essential to understanding the narratives. Possible futures, dystopic narratives, and alternative realities are used to change the present (Inayatullah, 2020).

In this educational path, Communication Design is used to validate speculation: the speculative process is correct when design artefacts can effectively convey it, and vice versa. Design should not be considered a mere self-reflective practice but a powerful communication tool to promote speculation, critical if not political positions (Mehl & Höfler, pp. 13–14).

Students are organised into small teams and taught to traverse disciplinary boundaries and embrace a critical stance towards an apparently fixed discipline, such as Communication Design. It is a matter of fact that Communication Design, usually intended as the area concerning the design of communicative artefacts and specifically of visual kind (Bucchetti, 2020, p. 117-118; Lussu, 2010), has nowadays expanded its boundaries, becoming more of an open context with blurred borders (Grimaldi, 2009).

The applied iterative process views experimentation as a pathway to finding solutions, even in domains where teachers, professionals, or students may lack complete mastery (Triggs, 2003, pp. 7-17). During the prototyping phase (from initial development to final stages), students adopt a 'learning by doing' approach, embodying something akin to the concept of "thinkering" (Antonelli, 2011), whereby a conclusive outcome is achieved through successive collective refinements. Berglund & Grimheden (2011, p. 737) affirm that experimentation and prototyping entail iterations of "trial and error", a pivotal aspect across various stages of response development, from design conception to ultimate implementation. The prototyping phase is crucial, and students are introduced to using Arduino and some coding

environments to promote technological fluency (Lukens & DiSalvo, 2012). In this educational setting, the goal is not to specialise but to become literate, as Reas (in Cangiano, 2016) explains. That means understanding which tools best bring concepts to life. Students are not restricted to using specific mediums; they are encouraged to explore different technologies to find the best fit for their project, whether print, three-dimensional space, or code.

The educational design process is grounded in an anti-disciplinary (Ito, 2016) and evolutionary concept, rejecting a rigidly fixed design methodology. Characterising the teaching approach as anti-disciplinary implies transcending mere multidisciplinarity, avoiding narrow specialisation within Communication Design education (Childress, 2016). Embracing an anti-disciplinary stance entails drawing from diverse sources to envision novel possibilities rather than confining oneself to a single domain (Brin, 2016). This pedagogical strategy, underscored by a critical perspective, prioritises unconventional problem-solving paradigms, encompassing problem-seeking initiatives and problem-posing inquiries (Blauvelt & Davis, 1997, p. 80).

The proposed methodology and educational objectives must acknowledge that the Final Synthesis Communication Design Studio in the third year represents the culmination of undergraduate students' academic careers. It serves as a platform for integrating the knowledge and skills acquired in preceding semesters, with coding and prototyping augmenting those associated with communication design and visual systems. Overall, the final project allows students to deal with a hybrid, transversal dimension of Communication Design, not necessarily closed in a specific area. In these terms, as Bernstein (2011) commented, "fluency with technology often draws on knowledge, skills, and approaches that cross traditional disciplinary boundaries."

By embracing a speculative design approach, students gain exposure to diverse media and tools that transcend traditional design domains and methodologies. This approach enables them to experiment with various methods, tools, techniques, and instruments and draw insights from other practices and disciplines. However, another pertinent consideration is the notion, as mentioned above, of technological fluency, which entails navigating between different domains and perceiving the boundaries separating inquiry areas as permeable (Crow, 2008). Lukens & DiSalvo (2012) affirm that speculative design and technological fluency are inherently cross-disciplinary and integrative.

In conclusion, Speculative Design offers a versatile approach that transcends disciplinary boundaries, fostering creativity, critical thinking, and technological fluency essential for questioning contemporary problems and addressing future challenges.

3. Anthropogenic Narratives: Case Studies and Exhibition

The learning process of the Communication Design Studio can be summarised in five main parts, as shown by the Speculative Overlapping Double Diamond model (Fig. 1) (Isidori, 2023): Exploration, Speculation, Communication, Interaction and Making. The overlap of the various phases, defined as Synthesis, is effectively the moment of transformation into key intermediate project outputs.

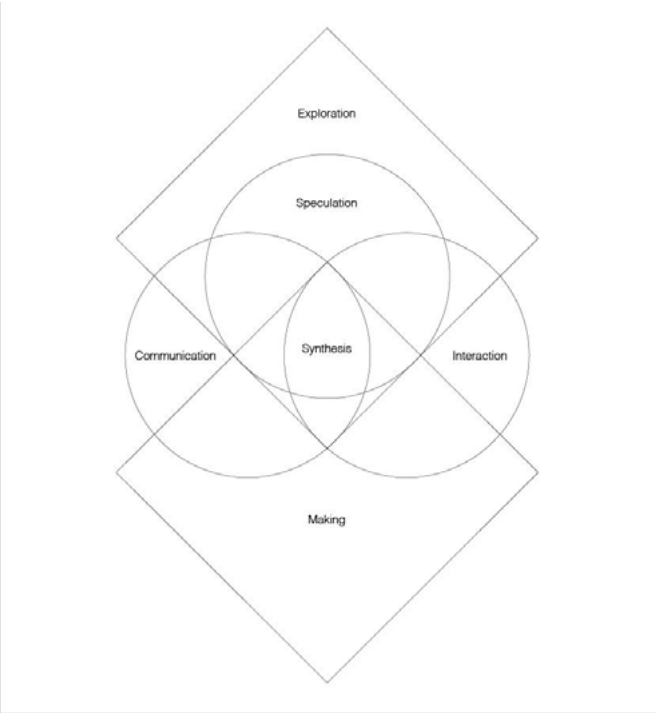

Figure 1. Speculative Overlapping Double Diamond Model (Isidori, 2023).

Students undergo diverse stages of the design process in each phase as they progress towards their final project. However, as emphasised by Frascara & Winkler (2008, p. 7), this process is not merely "reduced to a mechanistic set of steps", as "method without imagination contributes very little to the design profession and the solution of complex design projects." They collaborate in groups of 4 up to 6 individuals. Upon receiving the overarching theme (climate change), each group must delineate a specific perspective on the assigned subject (e.g., rocks, moon, sun or ice) and a corresponding scenario to address. Thus, they are tasked with identifying and dissecting a problem through analysis and research, operating within the realms of Exploration and Speculation. Leveraging human superstructures and organisations as valuable subjects, they employ fictional branding to "represent" their narrative, drawing upon competencies and skills acquired during the Bachelor's initial two years (4 semesters).

Subsequently, the focus shifts towards defining a concept and communication strategy and its multidimensional and multichannel execution (utilising touchpoints and selected media). Additionally, the students delineate the main functions, meanings, and contents of the Communicative Machine. Aligned with their concept and strategy, they devise a visual identity that ensures consistent communication across two- and three-dimensional outputs. They gain confidence in designing complex systems and transitioning into Communication and Interaction, where they begin synthesising the project.

A relevant phase is the prototyping one (Making), which encompasses both digital and analog realms. Students are encouraged to independently acquire any lacking skills, particularly in digital design, coding, and prototyping, while receiving guidance from instructors to refine their projects. Each member assumes a specific role within the group based on their interests and skills. Central to this critical pedagogy is the acknowledgement, rather than dismissal, of students' social experiences and cultural affiliations, which serve as lenses through which they perceive the world and mirror the audiences they aim to engage (Blauvelt & Davis, 1997, p. 80).

The primary outputs, the so-called Communicative Machines, are objects, installations, or interactive devices realised as prototypes for testing and verification. These objects are at the centre of narratives and intended to be like 'deus ex-machina', allowing the users outside the narrative to interpret the provocation and jump into the narrative. Other communication artefacts support this narrative; all the designed touchpoints ultimately enable the user to comprehend the world proposed (the story). All these objects, or

artefacts, produce the story's context appropriately and plausibly (Appadurai, 2013, pp. 355–364). Considering the given main subject (climate change), it was obvious to look for other kinds of stories and new worldviews to establish value and behavioural coordinates suitable for current and future conditions. The communication ecosystems (touchpoints, artefacts, interactive devices) are the narrative systems.

The premises that define each result are real: true data and actual risks humanity faces or will have to face because of climate change, conduct the scenario building and the concept development. This information is filtered through the judgment of an outsider spectator, who could be either victim, cause, or completely excluded from the phenomenon. It is preferable to consider different potential visions of the future as part of a participative journey toward centring a shared vision. When involving multiple stakeholder groups, it is important to acknowledge that each group may be concerned about a different set of issues and hold a different and conflicting set of values that could influence their choice. The intention was to promote an informed debate on a set of visioning scenarios and not to choose one in particular as 'the way forward' (Meadows & Kouw, 2016).

In the next paragraphs, we will briefly describe four case studies of the eleven projects produced in the 2022/2023 Communication Design Studio. The description considers the elements (moon, ice, rocks, sun) and their perspective on climate change. At the end of each case study, there is a link to a full description, images, and videos useful for complete comprehension.

If we consider, for example, the rising sea level, two completely different approaches and scenarios have been developed depending on the different positions and the involvement of the natural elements in consideration.

3.1 Moondo

The moon is an outsider participant in the climate change crisis. However, it contributes to the damages provoked by its effects. Its perspective is neither worried nor angry; on the contrary, with great irony, it takes advantage of the situation to make some profit, extending its influence and power.

The narration begins in 2030, and sea levels, triggered by global warming and moon activity, caused the flooding of several coasts and the abandonment of many cities. Moondo (Fig. 2) is a travel agency that takes advantage of the new environmental conditions and turns the submerged cities into perfect tourist destinations. The company offers numerous activities in each city, such as kayaking, paddle surfing, snorkelling on the surface, and scuba diving in the deep. Moondo transforms what would have been abandoned cities into the most fascinating places to visit. An interactive device, through the selection of geographical area, moon phase, and year of interest, allows the users to have a complete forecast of the floods that will occur within the next 120 years and find out the next available destinations and activities. The prototype has the shape of a computer, with a sloping top for the screen and a horizontal bottom for the controls. The structure was made of wood, then sanded, treated, and enamelled, with some elements in plastic and plexiglass. Arduino UNO Base connects the hardware with JavaScript, HTML, CSS software, and certain libraries and APIs. The libraries used were P5js, Jquery, and OpenLayers, which allowed the generation and interaction with the maps displayed during the interaction and made them available through a real-time data request service to Maptiler.

The final part of the Moondo experience consists of a video that, based on the user's choices, shows what activities they can do in a particular year, on a specific coast and in a certain phase of the moon.

3.2 I.C.E.

Ice's perspective is very different from the previous one though the project also reflects on the problem of the rising sea level. This element is indeed greatly affected by climate change. Humanity, blinded by its hunger for power, has made it weaker and weaker, dangerously close to extinction. Ice melting is probably one of the oldest and most known consequences of global warming. The persecution of actions that provoked such a problem has continued for years and years, fomenting a rage and a resentment that is now ready to come out.

I.C.E. (Insurge, Commit, Extinguish) (Fig. 3) is a terrorist organisation whose goal is to put to an end the harmful being that humiliates and destroys nature: humans. I.C.E. bombs are everywhere. Their timer lasts a few minutes and accelerates if anyone tries to get close. The only way to stop them is to stay still: place a hand on the icy surface of the device and stop doing anything that would make the crisis worse. As soon as contact ends, however, the time runs out again. The bomb explodes, triggering an environmental catastrophe at a specific point on earth, causing terror and destruction.

The bomb body, which hosts all the electronics, was modelled and printed in 3D. Once assembled, the cube was then covered with a black shrink sleeve. The final part, the ice in which the bomb was embedded, was made in epoxy resin. The device's functionality depends on a proximity sensor linked to a timer that triggers the bomb to 'explode'. When touched, a peltier cell makes the device appear cold, evoking the element of ice from which the message comes.

In addition to the bomb, the Communicative Machine consists of an old hackered television set.
The two elements communicate through an Arduino and a Raspberry PI. When the timer expires, the

Arduino contained in the bomb sends a signal to the Raspberry PI in the TV that broadcasts environmental disasters, interrupting the white noise signal displayed till then. The video and audio signals stored in the Raspberry PI were converted from an HDMI output to a SCART input to be displayed on the TV screen. The project is situated in a non-specific moment, taking reference from different periods and contexts to create a surreal world through a rich scenario that could be either in 20 years or tomorrow.

Authors: Ginevra Bernasconi, Giulia Bonalumi, Jacopo Domenichini, Agostino Sanna, Andrea Vitali. Source: https://anthropogenicnarratives.labsintesi-c1.info/projects/01_ICE.html.

3.3 Litia

As in the previous case, the project's scenario presenting the rock's perspective is situated in an undefined time context. Rocks are not affected by climate change. They have witnessed countless shifts in the environment, and this crisis is nothing more than one of the many that Earth has and will always experience. Human beings, however, have developed a feeling of anxiety towards this problem. To cure this disease, eco-anxiety, a company for self-care named Litia (Fig. 4), has created Specta, a device that looks at

climate change as the geological phenomenon of rock stratification. Climate change is not a problem if we look at it from a rock's perspective.

Thanks to Specta, eco-anxiogenic events are visualised as relaxing layers that expand the user's perception into a space of dialogue with the rocks. The device consists of a manipulable object that resembles a real rock in shape and size. By lifting and slowly rotating the device, the user can transform the vision of catastrophic events into rock stratifications. The visual effect that deforms the image was created using shaders, a special programming language that allows the same instructions to be executed simultaneously for every pixel on the screen.

The prototype's core is the controller board, specifically the QtPy ESP32-S2 model Adafruit7, which contains the data from the gyroscope and sends it to the base via an Arduino MKR WiFi 10109 board. A light sensor controls the transmission of information so that Specta only sends data when it is actually in use, not when it is on the base.

Specta was modelled and printed in 3D. Its aesthetic resembled that of a rock despite its clean and smooth surfaces, slightly smooth edges, and flat colours, which are very unnatural.

The experience is completed by tracking the amount of content the user has been protected from through an app that provides all the statistics on the device's benefits.

The real problem isn't climate change, an inevitable evolution of life on Earth. It's the way humanity looks at it that must change.

Figure 4. Litia: the device named Specta and a sequence of the eco-anxiety silencer. Authors: Francesco Bonetti, Federico Gajo, Emiliano Garibaldi, Enrico Isidori, Cecilia Pizzagalli, Camilla Tosi. Source: http://anthropogenicnarratives.labsintesi-c1.info/projects/08_LITIA.html.

3.4 Illumia

The project brings a similar message but in a completely different narrative system. Illumia (Fig. 5) is a machine designed to store data on the relationship between atmospheric composition and the colour of sunsets. It embodies the Sun's perspective, generating past and future sunsets from the star's birth to its supposed end. The story is set in a fictional 1984, in the Atmospherical Research Institute of America (ARIA), also a fictitious reality that gives truthfulness to the research at the base of the project. The narrative is set in a context that mixes historical events with imaginative ones, recalling elements from an actual past to build an alternative present and future.

The Communicative Machine consisted of a fictional digital archive whose shape and interface evoked the aesthetics of early computers. It was modelled and printed in 3D, divided into two parts due to its size. Its main components were a Raspberry Pi, serving as a server for a tablet, which also acted as a display, a mechanical keyboard for user inputs, an on/off button, and an LED.

After turning the computer on, the user can select a city from a predefined list and any year in Sun's past and future history. These coordinates are combined with the CO2, temperature, and humidity values identified for each year. These parameters represent the atmospheric components most sensitive to climate change and significantly influential on the colour of the sky. Once the user selects the preferred parameters, the screen displays the generated sunset and three graphs showing the different values of the three parameters over time. At the end of the experience, the user can also obtain a printed output version. The printout includes all the data displayed on the final screen with a message from the Sun itself.

The project aimed to help humanity reconsider the scale and impact of climate change from a broader perspective. The Sun has existed for 4.5 billion years, witnessing seven great extinctions and experiencing temperatures and conditions that humanity can't even imagine. From its point of view, the current climate crisis is an insignificant variation of the ongoing and perpetual change that the climate is constantly undergoing.

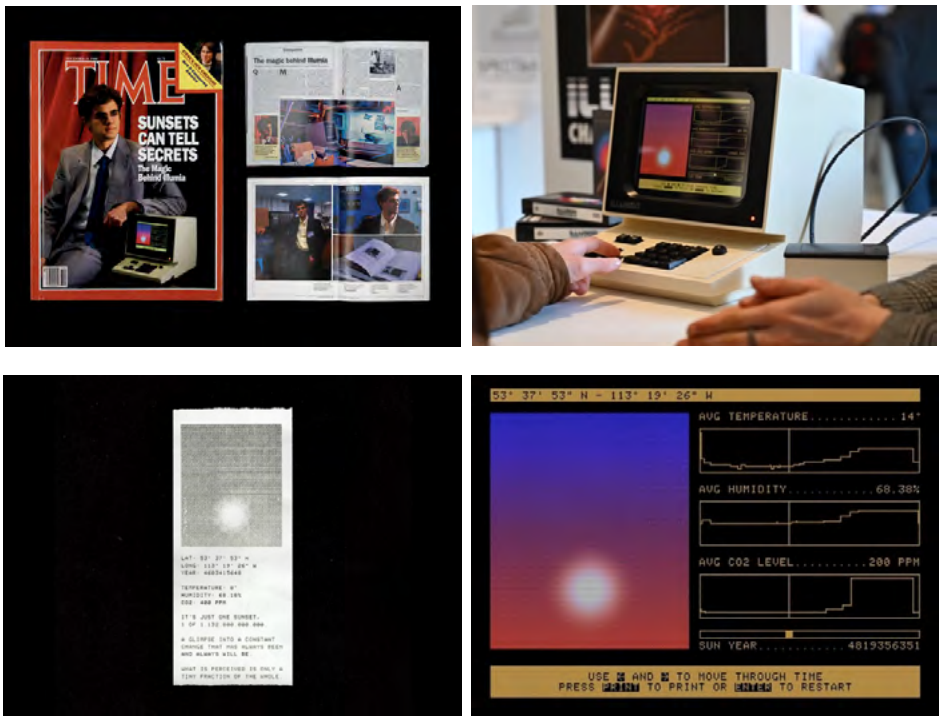

Figure 5. Illumia: cover and inner pages of a magazine setting the scenario, the Communicative Machine Illumia, the receipt with data and the message from the Sun, a screenshot of the interface. 3.5 The Exhibition and Some Considerations

Even if only as a fiction exercise, the possibilities offered by the projects stimulated a real dialogue toward unheard dimensions. Embodying a non-human perspective, each group showed how the different natural elements send signals and messages worth grasping as they can enrich our vision and awareness and guide us to restorative action.

Among the eleven, these four projects were conceived during the first semester's Communication Design Studio and then showcased in a one-day exhibition at Triennale Milano. The exhibition was emphatically entitled "Anthropogenic Narratives. Communicating and Experiencing Non-Human Perspectives" to summarise both the brief that conducted the learning process and the output. "Anthropogenic" refers to environmental change originating in human activity. The term "Narratives" refers then to the stories behind each project. The word "experiencing" referred not only to the design of experiences. The intention was to invite people to have a direct experience of these perspectives through the communication design ecosystems produced by the groups of students.

The exhibition/event lasted 9 hours and saw the participation of over 700 people who engaged in discussions with the groups about the projects, tested the prototypes, and provided feedback. In some cases, the scenarios were presented so convincingly in terms of communication and narrative that visitors thought they were real products or services.

The four shortly discussed projects developed using the presented pedagogy process generated responses in the meaning of Frascara (Frascara & Winkler, 2008, p. 11): design reduces problems and should always involve research. These designs were conceptualised from diverse perspectives, exploring varied scenarios and employing a range of technologies and media, encompassing both analog and digital formats. Consequently, each design necessitates theoretical discussion and practical validation through prototyping. Students were encouraged to experiment with visual communication, user interface design, and tangible interactions across two and three dimensions, inevitably involving the fourth, the one of time. This approach facilitated the exploration of unconventional methodologies and alternative design paradigms, fostering a critical examination of design values, forms, and representations (Johannessen, 2017; Bardzell & Bardzell, 2013).

Speculation and critical stances were translated actively using Communication Design but approaching design solutions as a hybrid discipline, which means it "allows to break out of traditional typologies, to experiment with hybridisations of formats, structures, and modes of expression" (Quaggiotto & Galasso, 2023, p. 220). By adopting this approach, students are led to assume a critical attitude towards their position as designers, reflecting their practice's social and political implications. Moreover, they also get used to managing their professional field as an open context, not necessarily closed by disciplinary boundaries but evolutionary by nature. Design speculations are not meant to give answers and certainties; they aim to imagine new questions and reflect on contemporary and future times.

The prototyping phase is significant since, beyond the reasons already explained, it generates organisational capabilities such as flexibility and requisite variety, becoming integral to products and processes. It also operates as an antidote against core rigidities through updates of new knowledge and new methods for solving problems (Leonard-Barton, 1995; Berglund & Grimheden, 2011). According to Berglund & Grimheden (2011), the learning model allows students to add benefits to teamwork, utilising each other experiences and perspectives, integration and synthesis, and socialising.

The material and/or digital prototype artefacts are essential in introducing students to a Research through Design (RtD) attitude (Zimmerman, Forlizzi, & Evenson, 2007). According to some of Giaccardi's (2019) statements, they play intriguing and essential roles in demonstrating possibilities, provoking and speculating on alternative presents or futures, evaluating design outcomes, and empirically testing hypotheses. Certainly, reducing the projects' development to a single objective is impossible.

4. Conclusions

Speculative Design is one of several disciplines that can help us to take action, anticipate the future, and explore what's possible. The future is not a passive destination but rather a continuous process influenced by our thoughts and actions in the present. Changing the probabilities of future outcomes and shifting towards preferable tomorrows requires connecting past actions to present behaviours. Imagination and the choices in people's everyday lives are the tools that make it happen.

As affirmed by Anagnostou, Karvinen and Vasko (2020), the concrete actions useful to create different futures don't need to be "grandiose intervention, they can also be gentle gestures". Despite its ironic and disruptive methods, the impact of speculative design is subtle and light. It quietly and discreetly touches the hearts of the people who participate in the project and find themselves indelibly changed by the experience. Stories are not vague; they have strong, real implications. As stated by Harari (2015), it is a fact that humans use their language not merely to describe reality but also to create new, fictional realities. Fiction is a powerful tool to create stories to believe in and to redefine the relationships between the elements of the world as it is. It turns out that the world as we perceive it is partly the product of human imagination.

> "We humans control the world because we live in a dual reality. All other animals live in an objective reality. We humans also live in an objective reality, but over the centuries, we have constructed on top of this objective reality a second layer of fictional reality, a reality made of fictional entities, like nations, like gods, like money, like corporations. What is amazing is that as history unfolded, this fictional reality became more and more powerful, so today, these fictional entities are the most powerful forces in the world. Today, the survival of rivers and trees and lions and elephants depends on the decisions and wishes of fictional entities that exist only in our own imagination." (Harari, 2015)

A meaningful event, as the exhibition entitled "Anthropogenic Narratives", enriched the memory with new information and redefined the relationships between already-known patterns so that these concepts can no longer be emptied of this newly attributed meaning. The change of perspective made it impossible to forget the point of view once it had been considered.

Each fiction created during the Communication Design Studio has had a concrete and powerful impact on the lives of those who participated in the project: students, professors, and visitors to the final exhibition held at the Triennale. Storytelling is a powerful tool for understanding the future and motivating the discussion related to a delicate and severe topic, such as climate change. Through participation, they had multiple benefits (Ackoff, 1993). They have a valuable learning opportunity and their commitment to action increases.

Reflecting on the project's impact within the educational context, what is the most interesting is the critical judgement that was stimulated in the students about their profession. These young designers became more than just capable operators: aware of the power their work has on people, they transformed into informed professionals, conscious of the ethical implications of their actions.

The feedback collected over the years from students and the audience in enhancement and presentation occasions (e.g., exhibitions, websites, social networks) confirms the effectiveness of the learning process and educational experimentation to create working prototypes. Students appreciate the anti-disciplinary approach in acquiring new knowledge and skills, directly verifying communication design's hybrid nature. At the same time, they learn to learn, accepting the challenge of a constantly evolving discipline and practice. In the comments to the various editions of the Communication Design Studio, they define the design approach as "extremely innovative" and "useful to learn by doing, work more independently, and deal with technologies never used before." Furthermore, the assignment of issues to develop through a speculative approach is interpreted as "stimulating" and "a challenge", which allows them to "find unconventional design solutions."

Conversely, a recurring comment concerns technical skills. Due to time constraints, many notions and knowledge are not provided during the course through frontal lessons, but their deepening is left to practice and individual initiative. This is particularly true regarding aspects related to coding or prototyping. Specifying that these comments were collected before the exam and the final exhibition is essential. Subsequently, following individual or small group interviews, these comments fade away. The completion of the experience and field verification make the educational model more evident to the students.

The practical verification, made with an external audience, finally allowed the students to verify the design hypotheses through the prototype. Its role is crucial to understanding the narrative through direct and personal experience. For students, this phase can be critical for questioning the design hypothesis. However, it also becomes the moment for self-criticism, for reflection on what has been achieved.

We firmly believe that an anti-disciplinary approach to design applied to a topic such as climate change can be effective in the teaching context. Thanks to a speculative framework, which allows, by definition (Dunne & Raby, 2013, p. VII), to create "Parallel worlds" or to make "The 'unreal' real", students could experience a perspective that traditional design wouldn't consider. By using the proper tools of Communication Design in an unconventional way, they could translate messages sent by natural elements to broaden a discussion that would otherwise be impossible.

About the Authors:

Francesco E. Guida, MSc in Architecture and PhD in Design and Technology for the Enhancement of Cultural Heritage. He is an associate professor at the Department of Design and teaches Communication Design at the School of Design at Politecnico di Milano.

Martina Esposito is a master's student in Communication Design at Politecnico di Milano. She is interested in communication design as a tool for applying research to the construction of the present and the future through imagination and storytelling.

Acknowledgements: The authors would like to thank the teachers and colleagues who worked during the last years at the Final Synthesis Communication Design Studio C1, Bachelor's in Communication Design, School of Design, Politecnico di Milano: professors Andrea Braccaloni, Pietro Buffa, Alessandro Masserdotti and Giacomo Scandolara, the assistants Marcello J. Biffi, Alberto Candido, Pietro Forino, Antonio Garosi, Michele Invernizzi, Adele Mazzali, Andrea Pronzati, Claudia Tranti, Ernesto Voltaggio. Launching, managing, and sharing an anti-disciplinary design practice in an educational context has been possible with them. Consequently, a grateful thought is for all students who, over the years, accepted the challenge.

KEYWORDS | UMWELT, MORE-THAN-HUMAN, DESIGN, POST-ANTHROPOCENTRIC, DESIGN

ABSTRACT | This paper begins by recognising our environment as a more-than-human community that is temporally and spatially situated. Within this community, all living beings are acknowledged as unique individuals encountering a reality that is shaped by their predecessors. As humans, we are part of this community, and we can choose to insert ourselves in a caring manner – or not. Acknowledging contemporary spatial practices' shortcomings, the study introduces a design approach inspired by Uexküll's concept of Umwelt to engage with the more-than-human reality. The first aspect of the approach emphasizes that each individual forms their own reality and that engaging with the subjectiveness of that reality is a participatory act towards the more-than-human community. The second aspect introduces the concept of 'intermediate zones', speculative spaces of interaction and mutual influence between Umwelten. These 'intermediate zones' seek to decenter human-centred thinking and foreground the entangled nature of our shared reality. By extending Umwelt's concept, the approach fosters a framework for exercises that explore these ideas, tested through Living Labs. In the Living Labs, an increase in the participants' sensitivity towards the more-than-human community was observed. The constellation of exercises centred around Umwelt has underscored the design process as a journey of engaging-with, rather than adhering to the conventional approach of problem-solving. We believe that the designer's role undergoes a subtle yet significant evolution: transitioning from a problem solver to a curator of ritualistic practices that incorporate and propagate more-than-human perspectives.

1. A Temporally and Spatially Situated Community

In every now-moment (Bird Rose, 2012), we humans are embedded in a whole set of more-than-human relations without which we could not live. Our lives are constantly entangled and supported by a network of animals (Van Dooren, 2010; Meijer, 2019), plants (Gagliano et al., 2017), bacteria (Margulis, 1998), fungi (Tsing, 2015), viruses, and soils, by the weather (Ingold, 2007) – but also by machines, buildings, computers and other forms of technology (Wakkary, 2021). The environment we live in is a communal effort of all these individuals whose entangled activities form the currents that push the continuous unfolding of the world forward – the worlding of the world is always a becoming-with (Margulis, Sagan, 1986; Haraway, 2016; Tsing, 2015; Disalvo, Lukens, 2011).

This network does not just lie waiting to be used by us – it is not a resource instrumental to human progress. This entire network has its own influence and formative power – and it shapes us not only in an idealistic sense but also in a material sense. For example, as Donna Haraway points out, consider that only 10% of all cells in our body contain our own DNA. The other 90% of cells contain the DNA of bacteria, fungi, and protists with which we share our environment but have thus also become part of our existence in a literal, material sense.

In focusing on two types of relationships, sequential and synchronous, anthropologist Bird Rose (Bird Rose, 2012) understands this multispecies network as a real community, in the complete sense of the word, a community that has its own history, existing of a group of multispecies individuals interacting in the now-moment. For what forms us all, our customs, our institutions, our way of life, is precisely the convergence and interlocking of all these elements. And, of course, in this network, the human is today a dominant weaving force, but he does not do that, in a Heideggerian sense, 'from the outside'. Although we often fail to notice, humankind is fundamentally shaped by the more-than-human network in which it is entwined.

From such a point of view, another-than-human being, such as a crow, is actively building towards the future of its surroundings. By living his life, that crow is helping to shape the framework within which all other beings, including humans, will shape their lives now and in the future. The crow always does this as an individual – situated and shaped by a unique spatial and temporally situated more-than-human community. That crow, after all, inherits (van Dooren, 2014) at birth a reality that is already structured by his crow predecessors but equally by past generations of rats and humans, and his life depends on his ability to insert himself as well as possible and thus contribute to shaping the fabric in which he is always embedded. This is a historical, temporal and located task, not an eternal return of the now, as our cyclical understanding of nature might suggest. It is a task in which this specific crow must demonstrate his own responsiveness and creativity.

When we, therefore, engage a specific location – professionally or otherwise – we are thus always interacting with the location's existing multispecies community. Relational networks are constantly being built on and around a site and in interaction with the site. Even by being present, we become active participants within these processes, integrating ourselves into the existing fabric, accounting for shaping a future more-than-human community. We can choose to do this in a caring manner or not – not because we are unique beings with a choice, but just because we are, at this moment, the most dominant species.

2. How to Engage?

In contemporary design approaches, however, there is little attention or respect for the existing more-than-human community. Such a lack of attention usually does not necessarily stem from ill will, practical objections, or time pressure but from the failure to see our surroundings as the multispecies spatially and temporally situated community that it is. In his book Ways of Being Alive (Morizot, 2022), Morizot points to a sensitivity crisis as the result of an impoverishment of what we can feel, perceive, and understand. This crisis of sensitivity stems from various factors, including technological advancements, urbanisation, and

predominantly Western cultural attitudes that prioritise human-centric perspectives over ecological interconnectedness. In short, we have created a condition in which we no longer need to be attentive to other-than-human life to thrive and are stimulated to turn inwards. The sensitivities of our human perceptual apparatus are shifting from a physical and multispecies world towards a digital one. We must relearn the 'art of attentiveness' if we aim to preserve and redefine what relationships we are able to develop with other living beings.

Our ability to form connections is hindered not only by a lack of attentiveness but also by the distance we have created between ourselves and all other living beings. It is a consequence of the humanist tradition embodied by Descartes' Bête Machine and Cartesianism (Stengers, 2007; Debaise, 2017; Driessen, 2020), constructing a bifurcation between humankind and all other life that is still deeply embedded within Western culture. For example, the notorious German philosopher Heidegger (Heidegger, 1995) reaffirms this bifurcation in a lecture series (1930) by claiming the other-than-human world is 'poor-in-world' while man is 'world-building'. We, humans, are believed to be the only ones with a history and the ability to creatively engage that history to construct a future. All other living beings are claimed to lack history and openness towards the future as they are unable to surpass their genetically determined path. In other words, we have constructed our Western reality on the belief that hard boundaries exist between us and other species while "our strong sense of difference from any other life-form, our sense of species superiority is a delusion of grandeur" (Margulis, 1998). When questioning these boundaries, it predominantly happens from our human-centred perspective, often resulting in affirming what is questioned (de Waal, 2016; Bridle, 2022). Although posthumanist studies of the last 30 years have increasingly countered this bifurcation, we simply forgot how we could relate, or in Ingold's words, correspond, with life surrounding us. In our day-to-day lives, we fail to notice how both we and they go along together in the current time (Ingold, 2017). In his book 'Being a Beast', Foster explores how he relates to the fox in his London neighbourhood, a badger family in his beloved Wales and three other earthly companions by immersing himself in the lifeworld of these individuals. "I share much more with a fox than with a fundamentalist [from Alabama]. I've lived and I live with the fox in an embodied, sensual world of wood and earth and bone and semen and cold. We met and meet in a real place" (Foster, 2016). Foster's attempt to become those animals, live or feed like them, is an immersive act of his whole bodily and sensory self. It is a radical and impossible attempt, but in its seriousness, it beautifully foregrounds the understanding of the broader phenomenological tradition that our sensory engagement is a participatory act. A focus on one's own bodily and sensory reality simultaneously broadens one's awareness by reimmersing one in a more-than-human community. "Far from restricting my access to things and the world, the body is my very means of entering into relation with all things." (Abram, 1997)

A third challenge hindering us from seeing and approaching our surroundings as a more-than-human community is the complexity and uncertainty it brings and our inability to deal with that. Being attentive and open to an existing community implies letting go of certainty. We have to come to terms with the fact that we will never fully understand the vastness of relationships that form a specific community, nor will we ever truly be able to predict how our actions will affect it. To solve this ignorance, we instinctively exert as much control as possible over the future, using assessment guidelines, nature conservation principles and norms or masterplans to form as complete a picture as possible of the ideal community we want to realise. We constantly readjust reality to match these understandings and visions and hence fail to be attentive and listen. According to Tănăsescu, the only way forward is to accept ignorance not as something to solve but as constitutive and structural. "The centrality of ignorance amounts to a perpetual commitment to observation and study, to finding out exactly what the nature of our community is. Given, indeed, both chance and change, this is a never-ending task." (Tănăsescu, 2022). Response-ability (Haraway, 2016) is never-ending. Constitutive ignorance and vulnerability are wedded, and accepting ignorance foregrounds the vulnerability we must exert when truly engaged in being part of a more-than-human community (Puig de la Bellacasa, 2021). It is a matter of openness to change, to relationships and the fluctuating nature of these relationships, and an openness to the future while being responsive to the past. It is a commitment to making choices in our engagement with the more-than-human community. This is inevitably associated with a degree of failure and force: making choices means not making other choices, and certain things will be excluded from the future community. We must be aware of this necessary force (Ginn et al., 2014). Just

because it is necessary does not mean it is unproblematic. This realisation should prompt us to exercise a certain care: don't let your choices be too burdened by a desired ideal image, but work uninhibitedly with what is now presenting itself. It is a commitment to "take on the fraught work—never finished, never innocent—of weaving new stories out of this multiplicity: stories within stories that bring together the diversity of voices necessary to inhabit responsibly the rich patterns of interwoven inheritance that constitute our world". (Van Dooren, 2014)

3. From Umwelt to Subjective and Intermediate Realities

To address the challenges above, we have conducted multiple experiments over several years, together with art and design students, to develop an open design approach based on two distinctive ways of creatively and speculatively engaging with Jakob von Uexküll's concept of Umwelt (von Uexküll, 1934). This approach aims to generate artefacts that transcend an all-too-human representation of our shared, more-than-human environment and help us, in the process of the making, to engage our struggles in relation to the more-than-human community.

In the book 'A Stroll Through the Worlds of Animals and Men', biologist von Uexküll takes a "stroll into unfamiliar worlds" by imagining a bubble around a creature that "represents its own world, filled with perceptions it alone knows." (von Uexküll, 1934) From this perspective, we see the world as it appears to the creature, and within this world, coined by Uexküll as the animal's Umwelt, we are only interested in what is relevant to that specific animal. Uexküll uses the sea urchin as an example to map out its relation to the world. Sea urchins are sensitive to light and perceive a darkening of their environment as an incoming threat and respond by moving their spines to the perceived threat. However, the sea urchin would react similarly to any sudden darkening of their horizon – be it a ship sailing above it or a cloud temporarily blocking out the sun. Uexküll illustrates this example by juxtaposing two illustrations. The first image illustrates an underwater scene as we would perceive it: we recognise a boat, a fish and a cloud. To underscore that for a sea urchin, these differentiations do not matter but are merely experiences of moments of sudden darkness, the second image pictures the same underwater scene with blobs taking place of the (for humans) recognisable elements. This illustrates that whilst we share the same environment, we all perceive and thus interact differently. As concluded by Lee: "The perceptual apparatus of an organism is directly related to its agency within the perceptual world it inhabits." (Lee, 2018). In understanding the intimate connection between an individual's perceptual apparatus, its agency and its surroundings, we come to understand that each individual inhabits, engages and actively forms their own reality. (de Roo, Ganzevles, 2023)

We distil two key notions from Uexkull's concept of Umwelt that shape our design approach. We expand upon the concept of Umwelt, extending its application beyond its original scope with a degree of flexibility. We intentionally avoid the distinctions between plants and animals in light of ongoing discussions in plant phenomenology (Brenner et al., 2006; Struik et al., 2008) and the evolution of our anthropocentric views on sentience and intelligence (Bridle, 2022). We also believe it can be beneficial to dissolve the distinctions between the living and non-living altogether, adopting an animistic approach to our environment, as David Abram propagates and spiritual ecology. While we recognise that abiotic elements such as the wind do not possess an Umwelt, deliberately exploring such fabula can aid us in the pursuit to counter anthropocentric thinking and decenter our ways of seeing.

The first key notion is the construction of a highly personal world through a sensory engagement with what surrounds an individual. We advocate an experimental approach rooted in the inherent subjectiveness of any individual to be-in-the-world, to highlight and explore this. For this reason, we developed a set of exercises inspired by radical observation methodologies specifically focused on our own Umwelt and subjectivity. These exercises range from listening sessions to observational walks or palette collecting. By focusing on our own subjective experiences, bodily reality and sensoriality, we acknowledge the existence of our Umwelt and its relativity towards the multitude of other Umwelts. As our individual activities form areas of greater and lesser sensitivity, this focus redefines the sensitivities within our own Umwelt beyond

what we usually use. In retraining our senses to be attentive to the more-than-human world, we counter the 'sensitivity crisis' as identified by Morizot and relearn how observation is always a participatory act. (Ratcliffe, 2008)

We devised these exercises so they lead to the production of artefacts using graphical, textual and audio-visual means or other artistic expressions. These artefacts are intended to translate the qualities and reality of engaging a more-than-human world – surfacing the producer's perspective and creative reaction to their surroundings, the synaesthetic reality of a place and the impossibility of completely grasping or understanding it. As such, they communicate the visceral reality of engaging a place and its inhabitants, stimulating a response-able engagement with the more-than-human community within the broader group of stakeholders of the general design process.

A second key notion is the visual intermingling of Umwelts. The drawings in Uexküll's book, exemplifying the Umwelt of a sea urchin or a mollusc, are interpretations of the perceptual worlds of these animals, projected over how we would perceive that environment. These drawings do not aim to show reality but highlight different relevant perceptual cues within the environment for that other-than-human, transposed on how we perceive the environment. In creating these visual overlays, Uexküll unintentionally provides an intriguing pathway to explore as part of a more-than-human design approach (de Roo, Ganzevles, 2023), as there is an inherent quality in these in-between realities. We, therefore, developed a guide to develop these transpositions and leverage their qualities. Starting with an analysis of the other-than-human individual and a reading of the landscape from the individual's perspective, we work towards developing a speculated reality in between our subjective reality and the subjective reality of another-than-human individual. We call these in-betweens 'intermediate zones'. These 'intermediate zones' can take various forms, from written documents to graphical or audio-visual interpretations to site-specific interventions, provided that they encompass what makes tangible the perspective of another and immerse us in their Umwelt through our own. Following Shores' expansion of the Umwelt towards becoming-animal of Deleuze & Guattari, we propose that these 'intermediate zones' can also be realised in actually transforming our bodily reality towards the bodily reality of the other-than-human. Instead of taking on the identity of another creature, becoming-animal rather involves trying to draw near enough to it so that one enters into a "shared zone of proximity". (Shores, 2017)

The artistic quality and the speculative act of creating these 'intermediate zones, knowing full well that they will not – and can not – be a complete transposition or transformation, foreground structural ignorance and speculation as a tool to engage the more-than-human world. It is exactly this speculative character that brings out, in Forlano's words, the "imaginative and rigorous ability to defy the constraints of a typical design brief". (Forlano, 2016)

4. Living Lab

To empirically investigate the effects of our approach, we established two Living Labs over one academic year. Living labs refer to collaborative sessions built on a process of design research. The consequences of various design scenarios are actively discussed and evaluated (Lupp et al., 2021). These sessions aim to unlock knowledge, dialogue and co-creation processes, allowing iterative feedback loops. A derelict industrial marshalling yard was selected for testing as the contrast between the sites' harsh urbanised characteristic and the unintended non-human use foregrounds the existence of a more-than-human community in which we are no active participants.

Each Living Lab was a six-credit interdisciplinary course taught on-site once a week in 4-hours blocks. The second- and final-year bachelor students participating came from various academic backgrounds, ranging from art to design disciplines. The overall goal of the Living Labs was to test the developed exercises around the concept of Umwelt based on the students' retention of key concepts and realisation of a shift in sensitivities as designers towards multispecies communities through ongoing and end-of-course evaluations with an invited jury.

Students were asked to fill out a questionnaire to establish a baseline of their knowledge. Students were asked to use a notebook to document their thoughts, ideas and experiments throughout the course. We emphasised the production of artefacts through various exercises to move the research forward. The exercises forming the design approach aim to stimulate students' sensitivity towards the more-than-human community, encourage them to integrate themselves within that community, and propose design interventions exemplifying and communicating their relationship with the more-than-human community. A selection of exercises is detailed below.

The first two weeks introduced key concepts in posthumanist discourse and let students get acquainted with the site. We invited species experts to uncover traces left behind by other-than-human actors and to expand students' knowledge of the site. Under their guidance, students first-handedly experienced the impoverishment of their sensory sensitivities compared to the abilities of our experts to, for instance, detect the smell of a fox.

By introducing exercises in the form of non-human persona cards (Tomitsch et al., 2021) and species passports (Weisser, 2019), students were stimulated to expand their knowledge of the actors on the site.

In the subsequent four weeks, students were given exercises to explore the site and attune to it from the perspective of their own Umwelt – referencing the first key quality we identified in von Uexküll's theory. These exercises consisted of observation exercises (Bodily Observations, EX1) in various forms, focussing on our senses as well as the site. They help students discover the subjectivity and sensitivity of their senses and introduce observation as a participatory act. Senses enable interaction, bind the individual to material reality, and help to stay with the trouble. As such, cultivating our senses becomes an ethical act of more-than-human acknowledgement.

Through the exercise of palette collecting (Palette Collecting, EX2), students were challenged to collect objects or observations on site. Collecting, following an intuited pattern, frees us from our expectations and enables us to form new subjective perspectives and understandings. Moreover, ideating patterns in the collections activate long-term memory as our personal history informs the patterns we see and develop. Rearranging the found elements gives them meaning. This stone is no longer just a stone; it's a stone that stands in relation to other elements because, by collecting it, you introduce these relations. It is a way to acquire and express identity together with a location, eventually strengthening your situatedness in the physical world. Collecting is a creative engagement weaving your story through the landscape, resulting in a landscape that is fully alive and active.

A third exercise meant to develop a sensitivity towards the derelict marshalling yard was observing one specific actor (One Actor Observation, EX3). Daily, we encounter other-than-humans but often rely on our preconceived notions to 'classify' and move on. For instance, we roughly know how a feral pigeon looks and how it acts and are therefore less attentive to that specific pigeon in that environment. The observant transforms from an alien and accidental observer to an immersed individual, transforming the relationship we have with the environment to which that individual belongs.
In the next four-week period, we introduced other exercises that relate to the idea of 'intermediate zones' that we drew from the second key quality we described in von Uexküll's conceptualisation of Umwelt.

An introductory exercise was Multispecies Storyboarding (Multispecies Storyboarding, EX4). Drawing from the practice of storyboarding in HCI and design (Truong et al. 2006), this exercise revolves around understanding how actors interact with a spatial object. The goal of this tool is to acquire a better understanding of the importance and appearance of the object within different Umwelten by retelling a narrative from different perspectives. Where humans approach an object from their perspective, experiences and viewpoint of utility, other-than-human actors can dedicate a completely different meaning or utility to that same object. For instance, where humans might view a shed primarily as a storage space, other-than-humans, such as crows, see the structure as a safe place to land and observe their surroundings. By identifying the role of the object for multispecies interactions, a layered understanding is built around this object, where various Umwelten overlap – informing the creation of 'intermediate zones'.

In this exercise, it is possible to understand how abiotic elements interact with the object, for example, how the course of wind changes due to the shed, leading to ripples into other Umwelten. These insights can then inform speculations about potential acts of care that could influence existing relationships or pinpoint moments in each individual's timeline that hold promise for connection.

In 'Appropriating Non-Human Form' (Appropriating Non-Human Form, EX5), we speculatively explore becoming another-than-human being as a creative and liberating way to bind the bodily self to the bodily reality of the other-than-human individual, eventually resulting in an 'intermediate zone' in which possible entanglements can be ideated. "The ways in which, inevitably, I perceive and describe a badger's scent world involve things that have no representative at all in the badger's own world. They are purely human artifice (...) I can't know what the immediate burst of a dog's mercury scent does in a badger's brain, but does it really matter?" (Foster, 2016) A gap between you and the other will always exist, but by taking on other-than-human forms, we inch closer to each other by creating an 'intermediate zone'. In changing our morphology and sensory capacities through the use and development of sensory-shifting tools and prosthetics, we are able to perceive the world more like other-than-human beings. In focusing on the meanings these perceptions have and the effects they generate in us and the other-than-human individual, we can give meaning to that 'intermediate zone'. In these attempts, we do not aim to replicate an experience or become that being altogether; we strive to creatively extrapolate that experience into a mediation, a space for new meaning and relationships to emerge.

We can employ technological tools that extend our senses to aid these exercises. Incorporating existing and emerging technologies allows us to decenter our human perspective temporarily. For instance, we understand our site differently by using night vision cameras and thermal optics. Using LiDAR technology, we can inch closer to understanding how a bat might perceive the environment. Furthermore, the emerging field of generative AI opens up a vast array of possibilities for sensing, decoding and visualising these intermediate zones.

The final exercise provided to the students was to explore entangling Umwelten (Entangling Umwelten, EX6). Building on desk research captured in the species passports and non-human personas and by comparing the sensitivities inherent in our senses with those of other-than-human actors, infused with the learnings from the previous exercises EX4-5, we can speculate on the different perceptions of a specific context. These speculations should not only account for the primary functions of the senses (i.e. locating food, finding kin) but should also consider how the anatomical structure of the individual might influence the possible sensitivities of the senses.

This speculative exploration requires rendering intermediate zones visually as the designer has to mediate between representing their own Umwelt and questioning how to represent the Umwelts of their chosen actors. This speculated entanglement provokes opportunities to consider "numerous overlapping worlds in which many kinds of things and many ways of seeing and being are possible" (Bridle, 2022). This comparative analysis aims to illuminate potential conflicts and opportunities within our co-existing effect-worlds, offering a deeper understanding of our shared environment from multiple perspectives.

5. Reflections

By incorporating the concept of Umwelt into our exercises, we have anchored our design approach in Art Science – a hybrid practice where artistic production and methodologies are fused with scientific research and principles. This hybridity is crucial as speculative 'intermediate zones' can only effectively contribute to decentering the design discourse when deeply rooted in biological realities. This grounding ensures that these speculative environments are not only imaginative but also resonate with current scientific understandings of the more-than-human world, thereby enriching the exploration in this field. This groundedness is achieved by drafting lifecycles or species passports and collaborating with biologists, trackers or nature conservationists. At the same time, this approach ensures ecological professionals' involvement and remaining interest, evidenced in both Living Labs. Concurrently, the development of

‘intermediate zones’ for decentering the human crucially hinges on the experiential component, as underscored by DiSalvo and Lukens (DiSalvo, Lukens, 2011). This aspect is vital in ensuring that these zones not only conceptually but also tangibly shift perspectives away from a human-centric view, fostering a more immersive and engaging experience that resonates with and challenges the audience.

While the group of exercises strikes a balance between speculation and grounded research, individual exercises often lean more heavily toward one specific aspect. Allowing participants the freedom to choose their path through the exercises opens up opportunities for exploration and personal engagement with the material. However, we noticed the students tended to gloss over the science/research-oriented exercises and relied on preconceived ideas and simple anthropomorphisms to tackle the speculative parts of the design approach. This was more pronounced in the projects of art students. This could be correlated to art studies, generally having a less focused scientific groundedness. One project focused on feral pigeons and, following detailed observations developed a headmount for humans to see the world as a pigeon. In this case, the project did not dive deep enough into the different senses of a feral pigeon in relation to its life cycle and day-to-day survival to realise an ‘intermediate zone’. Another student created an Instagram page to share insights on the speculated emotional condition of the wind, yet overlooked researching fundamental meteorological phenomena driving local wind patterns, like thermal shifts from differences in paving materials. Therefore, this exploration felt flat as it couldn’t be effectively linked to the site’s materiality and was disregarded further in the process.

While we support tailoring the design approach to an individual’s project – with room to introduce or exclude exercises as seen fit – the aforementioned observations highlight the importance of engaging with exercises that significantly differ from one’s own expertise. Neglecting this leads to an unbalanced approach that hinders the exploration of ‘intermediate zones’. Following other design approaches, we strongly advocate for an iterative process, as the knowledge developed in each step can strengthen or steer preceding exercises in new directions.

During the two Living Labs, the students started to pose critical questions as they developed an increasing sense of curiosity and wonder. “Why do we attribute so little value to what already exists?” “Why has the publicly accessible part of the site been cleared of spontaneous scrub vegetation?” Many students were emotionally shaken when a bulldozer came and eradicated most of the existing life to establish a temporary parking lot. This common practice does not normally elicit the same strong emotional response or feelings of grief. The zones on the site, still awaiting ‘clearing’, slowly drew the students’ attention, as these zones felt like the more-than-human community could still further develop – that there is a starting point to build relationships.

Considering the short time frame of the Living Labs as well as the beyond-human scale of the site, students could never become experts of the site and its more-than-human community. Despite that, students did manage to develop a sensitivity towards the existing community. In one project, a student connected his family history to the researched history of the Italian poplar trees on site. As a landscape architect, he abstained from drafting an architectural plan for the end-of-course evaluation. Instead, he developed several proposals, some of which consolidated his bond to the poplar trees, aimed at fostering the flourishing of the trees, notwithstanding the substantial and forthcoming transformations of the site.

Students indicated several reasons as to why their sensitivity grew throughout the Living Lab. Some referred to specific exercises as pivotal moments, and other students highlighted the encounters these exercises triggered. Others simply referred to immersing themselves in the more-than-human community by spending 30+ hours on-site thinking about that topic. Throughout the 10 weeks, the concept of a more-than-human community took root in the students' minds, leading us to argue that the design approach laid the foundations to become a reponse-able actor within that community.

The growing sensitivity to the topic made some students question conceptualising physical interventions on-site for the end-of-course evaluations. They posed that it contradicted the ideological objective of the assignment, where inscribing ourselves in the more-than-human community meant not yet again to

produce something. “We already make too much; can’t we just not make anything?” Following this enquiry, some students focused on the observational exercises - developing artefacts that foregrounded their personal encounters with the site. This led to interesting discussions, linking the critique with the idea that humans are somehow always an ecologically destructive species (Tănăsescu, 2022), that human actions are somehow unnatural (Vogel, 2011), or the perception that the thriving of a more-than-human community does not involve some sort of violence.

> “Flourishing always involves a constitutive violence; flourishing does not imply an ‘anything goes’ free-for-all but requires that some collectives prosper at the expense of others. This perspective requires us to see non-humans not always as victims nor humans as perpetrators. Rather, flourishing involves many species knotted together, often imbricated in human landscapes or economy, working with and against other multispecies assemblies.” (Ginn et al., 2014)

These debates led us to question the design process in the context of response-able engaging a more-than-human community. Do we keep understanding design as a process working towards some sort of pivotal interventionist moment to solve a problem, or should we understand the moment we enter the site as the start of the intervention? How can we even speak about a pre-intervention stage in this post-anthropocentric world? The learning process to engage a more-than-human community becomes the intervention to “increase the affordance of the built environment to life and to expanded forms of cohabitation”. (Leveratto, 2024)

The accumulation of artefacts gathered in the provided notebooks was crucial for initiating and conveying this transformation, as it reflected the students' efforts to interact with and respond to the existing affordance of other-than-human individuals. Our understanding of the artefacts developed further during the Living Labs, particularly as some students engaged in performative acts, dug holes or cultivated plants from cuttings. Others pursued more expected creative endeavours ranging from drawings and sketches to audiovisual works. Expanding on our notion of artefacts, we regarded all these pursuits as results of the process of engaging with the more-than-human. Thus, we experienced how design in the more-than-human reality mirrors the practice of gardening (Cléments, 2015), slowly attuning the self and the community to each other through incremental acts. Each act is an opening up to that community, to remain attentive and to acknowledge we are learning to find our place precisely because we will always be unable to know exactly what that means.

Through interactions with the more-than-human community, the role of the designer transitions from external entity with a defined objective to an active participant within that community, and ideally, its advocate—capable of voicing concerns beyond human-centric ones and navigating the intricacies of the multispecies interactions amid spatial transformations.

6. Conclusion

This paper begins by recognising our environment as a more-than-human, temporally and spatially situated community. Within this community, all living beings are acknowledged as unique individuals encountering a reality shaped by their predecessors. The ability of an individual to survive and thrive within that community depends on their ability to insert themselves and shape the fabric in which one is found. This is a responsive and creative act. As humans, we are part of this community, and we can choose to insert ourselves in a caring manner – or not. Contemporary spatial practices indicate our struggle: we often fail to recognise our place within this community, to see ourselves as equals within this community, or struggle to engage with the structural ignorance that comes with this.

To address these challenges, we developed a design approach based on two distinctive ways of creatively and speculatively engaging with Uexküll’s concept of Umwelt. The first aspect of our approach emphasises that each individual forms their own reality and that engaging with the subjectiveness of that reality is a

participatory act towards the more-than-human community. The second aspect introduces the concept of 'intermediate zones', speculative spaces of interaction and mutual influence between Umwelten. These 'intermediate zones' seek to decenter human-centred thinking and foreground the entangled nature of our shared reality. Through these lenses, we interpret the concept of Umwelt beyond its original scope, offering a framework for exercises that directly or indirectly relate to these key features. The effectiveness of this approach has been tested through Living Labs, providing insights on the exercises and the overarching shift in sensitivity towards the more-than-human world.

In the Living Labs, we observed an increase in the participants' sensitivity towards the more-than-human community. Not only in acknowledging the existence of that community but also in recognising our non-central or relative position within it. While it is premature to conclude that this heightened sensitivity translates into a lasting, productive force in the subsequent design attitude (given the limited scope of the living labs), our use of Umwelt as a red thread throughout the various exercises has contributed to an increased awareness of the 'intermediate zones' where designers operate.

Moreover, the constellation of exercises centred around Umwelt has underscored the design process as a journey of engaging-with, resembling the nurturing practices seen in gardening, rather than adhering to the conventional problem-solving approach. In this context, we believe that the designer's role undergoes a subtle yet significant evolution: transitioning from a problem solver to a curator of ritualistic practices that incorporate and propagate more-than-human perspectives.

Further research is required to evaluate the implications of this evolving role of the designer on concrete design proposals and to understand its applicability in a context where other challenges and limitations are at play. However, our findings suggest a promising avenue for redefining the designer's role in an entangled, multispecies reality. This role emphasises the importance of continuous, sensitive engagement with our environment, in which design is seen as a collaborative and caring act that accounts for the innumerable voices of the more-than-human world.

KEYWORDS | INSECTURE, INTERSPECIES–INTERACTION (IX) DESIGN, BEHAVIORAL-MODEL, INSECT-EMPATHY, INSECT-ETHICS, INSECT-CONSCIOUSNESS

ABSTRACT | Using insects as the primary subject, this paper presents a speculative, biology focused model of performance and design-based thought and creativity. It is supported by the expansion of the Goethean method of biological analysis and defines a new discipline of interspecies-interaction (IX) design. This is best represented by the following works: Mao Moth Laos, the documentary films by Tokuro Oka and Mao Kobayashi (2019), and Insect Viewing Apparatus (IVA), a tool by Christopher Mark Kaltenbach (2016).

This discipline is juxtaposed with the problem of how to understand and creatively use insects in ways that generate pro-environmental advocacy from an external audience and considers how the concepts of empathy, consciousness, and ethics, as they apply to insects, aid in that advocacy work. This provides a steppingstone to move beyond the confines of those who solely advocate on behalf of insects in favor of an idiosyncratic exploration and celebration of insect form and behavior that in turn manifests a unique behavioral model between human and insect.

Furthermore, this research clarifies and expands upon the insect-based design and research strategy discussed in Kaltenbach's dissertation. It is situated within his definition of Design Applied Environmental Entomology: "…aesthetic approaches of framing and interaction with these animals. Set against three commercial industries of bioengineering, food manufacturing and pet breeding…[implying] another approach to sustainability" Ultimately, this model demonstrates "enthusiasm, care, and value" for these animals and provides new ways to contemplate their beauty and mystery.

1. Introduction

The title of this paper Insecture is a neologism first coined in Christopher Mark Kaltenbach's PhD dissertation under the same title (Kaltenbach, 2019, p.3). The addition of the "-ure" suffix to an animal name that defines any class of arthropod was made to capture a conceptual idea about a broad set of design engagements ("act, process, being") (Merriam-Webster, n.d.) with and for insects. It is an aesthetic contribution, enhancement, and promotion of these animals and the underlying common good they bring to the planet's ecologies and societies. As a verb and noun, in this paper, it is a broad umbrella from which to introduce a specialization of creative works that use performative strategies such as dance and product design to envision new behavioral realities between humans and insects. This design specialization is described here as interspecies–interaction (IX) design.

The two creative and biology-based works put forward as representations of IX design are: the documentary films Mao Moth Laos by Tokuro Oka and Mao Kobayashi, and a tool called Insect Viewing Apparatus (IVA) by Christopher Mark Kaltenbach. The uniqueness of these performative works propelled the definition of this design discipline, which is enhanced and aided by a variety of mediums and devices, such as light, video footage, tool and/or spatial envelope. The objective in both is to create a new appreciation, inspire empathy and wonder from the interplay of viewer/participant/performer and insect. Ultimately, the key question is, can these types of invented, artificial interactions with insects— performance- and design-based works— motivate pro-environmental action in the public?

One does not have to look far to find a similar model that researchers have identified as generating public appeal for conservation efforts (another form of pro-environmental advocacy) for the zoo. Here specific characteristics of the contemporary zoo have been identified to foster a positive appeal for individuals. Beyond these animal enclosures, circuses, marine mammal parks and aquaria are also spaces for interacting with "wild", un- or semi-domesticated animals. Contentious as these venues may be, these likewise provide important models for future analysis.

Within the fields of art and design, much has been written on the subject of animal integration into art and design work (Brady, 2010; Aloi, 2015; Mitchell, 2016). Little, however, has been published on insects in creative disciplines (Barrett and Tierney, 2022), especially as it pertains to their interactive, performative potential. The discipline of IX design described in this paper, is currently unable to assert if the work presented offers the same opportunities to invoke pro-environmental or conservation messages as those found in a zoological model. With that said, recent research in insect consciousness is providing another pathway for garnering a better appreciation for these animals, which may aid in messaging to the public the importance of these animals, and hence the need to advocate on their behalf.

The expectations of purpose that govern Mao Moth Laos and IVA are speculative, because the immediacy of the performative activity, the result of presenting these impromptu interactions between human and insect is neither fully known or complete. Their speculative nature can also be understood as instructional devices for the dancer or designer in order to create future works, or to have the potential to motivate the viewer or participant in some positive action, ideally advocating for the preservation of their natural habitat. Ultimately, what these works present are models of action within a process of becoming. This type of creative work comes closest to resembling the performance art-based strategies popularized in the 1990s, as described in Nicolas Bourriaud's book, Relational Aesthetics (Bourriaud, 2009).

Speculative approaches in the field of design have a rich history dating back to the drawings of the late 18th-century French architect Étienne-Louis Boullée, which the Australian art critic Robert Hughes aptly described as "paper architecture" (Hughes, 1980). As well as the more recent practice of British designers Anthony Dunne and Fiona Raby, whose "supernatural, future fiction" (Kaltenbach, 2017, p.42) projects and collaborative teaching with students, which spans more than twenty years (Dunne and Raby, 2013), introduced a type of design that blurred its intentions with contemporary art strategies. In general, speculative design can also be defined as work that is waiting to or is not intended to be made (remaining

as a 2-D rendering) or mass produced (remaining as a one-off object); it also has the potential to imagine alternative societal norms, conditions and/or issues. Today, this mode of art- or design-based work continues to evolve.

Furthermore, it must be acknowledged that these projects function as contemporary, urban mediators between individual and insect. The interpretations of these animals and the decisions of how one should interact with them is a by-product of the human-made environment and its social milieu, including influences from Asian cultures. This perspective can best be understood using Steven Vogel's concept of a "social construction of nature." (Vogel, 2016, p.33) It establishes that the "way in which nature is experienced changes over time and is closely related to changes in social structure and worldview, this does not mean that nature itself, the thing that is experienced in different ways by different societies, changes." (Vogel, 2016, p.35) Similarly, the works by Oka, Kobayashi and Kaltenbach are also social constructions, fabricated interpretations of these animals, separated by the actual lived experience of the insect itself. Whether or not their perspectives on insects represent broader social structures or worldviews will be left to future analysis.

2. Insect Empathy + Ethics + Consciousness = Pro-Environmental Activism?

When it comes to placing animals at the center of pro-environmental activism, often their plight and the larger environmental issues they come to represent become mired in debates between political, agricultural, industrial food animal production constituents, to name a few, and those who seek to promote their autonomy. The long-held beliefs that animals, like many of the earth's resources, are meant to serve and sustain human life, become irreconcilable against those who hold animal existence and their interconnectedness within the earth's ecologies as a priority over commerce-based mandates that either benefit from their eradication or use as a commodity.

Environmentalists, conservationists, and vegetarians or vegans have largely depended on empathy and the promotion of an ever-evolving field of animal ethics as tools for advocating for the welfare of animals. Insects have recently found these advocates calling for the ethical treatment of them, especially as it pertains to food production. As subjectivity forms our understanding of animals, it is necessary to recognize which insects are perceived useful. For example, the bee has higher standing than the locust in areas of North American agriculture production due to the bee's function as a pollinator. A utilitarian function that aids the productivity of humans is one area of valuation in an otherwise socially constructed value system. Insects, like the idea of nature, "boils down to nothing more than what our culture makes it out to be" (Kahn and Kellert, 2002, p.153). (Kaltenbach, 2019, p.72)

Circuses, zoos and marine parks provide immediate and intimate encounters with undomesticated animals. In a 2019 study, researchers found that repeat visitation to a zoo leads to an accepting attitude towards animal conservation efforts (Andrea and Eduardo, 2002, p.10). Even more telling was when zoo staff interacted with the public in an educational manner, the zoo experience was greatly improved; they "found that public animal training and public animal training with interpretation produced more positive zoo experience and perceptions of exhibit size than passive exhibit viewing or interpretation-only sessions" (Andrea and Eduardo, 2002, p.10). This is an important observation, as it demonstrates that in some instances the observed interaction between an animal caretaker and the animal itself can generate stronger feelings of empathy for the animal than if the animal was left alone in an enclosure.

Outside the interactive experiences found in the zoo environment, where insect exhibits are rarely included, what opportunities does the public have to be informed by these small, often tiny animals in a controlled space? There are natural science museums that showcase dead specimens, or sometimes a lepidopterarium with live butterflies. In Japan, there is a type of pop-up beetle petting zoo that periodically opens in a department store's vacant floor. These provide the public, especially children, valuable hands-on exposure to these animals (Kaltenbach, 2019, p.228-229). Beyond these examples, the insect in most instances is stigmatized, making the possibility to change people's opinions in an educationally interactive public experience challenging.

Perception and Proximity: the Difficulties with Insect Empathy

Most animals have the capacity to allow people to feel some level of personal empathy toward them, and some more than others, such as a family pet. There are two important aspects for this relationship to be established. The eyes of the animal are one and the other is feeding an animal. Most animals can indicate recognition with one another through eye contact. The eyes of warm- and cold-blooded animals are relatively the same in that there is an eyeball with a pupil inset in an iris and sclera (often the two are the same color). This eye can move, and the pupil can change in size and shape. However, when it comes to the entire face of the insect, it is difficult for humans to discern. The components of its face provide no clues to establish if the animal is aware of another's presence. This is due to the abstractness of the insect's facial features, which makes the eyes and mouth difficult to identify. The single continuous color of the insect eye never provides a visible change. As the mouth opening of an animal is usually formed by a defined edge, like lips or a beak, the insect provides no clear demarcation. Also, since a mouth is typically used for some level of defense, it can be difficult to know which end of the insect to stay clear of.

When the mouth of an animal has been established and one finds themselves in a situation to feed it directly (which is usually the case at a zoo, petting zoo or even a koi pond), the exchange can be thrilling, especially when the tug of the animal is felt, its will being transferred through a leafy branch to the hand; there is an unmistakable feeling of momentary connection. There are few insects that provide that visceral immediacy in this food exchange. For these reasons it can be argued that it is difficult to feel empathy for or from the insect, hence the difficulty in developing a relationship with it. These observations provide part of the critical rationale to justify the need for design to reframe the insect.

In addition, we typically do not allow animals to initiate physical contact. We make the first advances by petting dogs, horses, rabbits and when at the zoo, the handler controls the animal and the situation by directing us where and when to stroke the animal. Insects on the other hand, find us, without us realizing it. They land on our shoulder, crawl up our pant leg or cling to our clothing when brushing up against an object. Typically, it is only when we feel the uninvited tickling of the tiny legs or the proboscis of the mosquito piercing the skin that we shudder and cringe. The feelings of fear, pain and annoyance are generally the first to come over us. However, when a person approaches an insect and initiates physical contact, the experience can be very different, even enjoyable. (Kaltenbach, 2019, p.72)

Insect Consciousness: Scientific Analysis vs. Social Construct

Can insects be considered sentient beings? Scientists have found it difficult to establish what kind of subjective experience insects have. Researchers have argued that for insects to feel pain they would need nociceptors (pain receptors), which they do not have. However, they do respond to heat, cold, and mechanical stimuli. Also known as nociception behavior, Zeder reports, "It was found that a single class of neuron (class IV multidendritic neuron) is sufficient and necessary to cause this nociception behavior." (Zeder, 2015, p.3191). The insect is "genetically programmed" with the behavior and is not actually thinking about the pain or recognizing that it is feeling pain. Nociception is not pain, it requires an emotional response, which insects are unable to convey (Hwang et al., 2007).

A paper published in 2016 by researchers Barron and Klien suggest that there be an "alternative approach to studying the capacity for subjective experience in invertebrates" (Barren and Klein, 2016, p.4901). They

proposed “arguing about what subjective experience is, and what is capable of it, is most productive when appealing to empirical neuroscience” (Barren and Klein, 2016, p.4906). Using various methods, they determined different levels of subjective experience and that “there are many classifications, but each posits a basic form of consciousness that consists of a direct awareness of the world without further reflection upon that awareness” (Barren and Klein, 2016, p.4901). Furthermore, “the insect brain resolves action and target selection, processes sensory information, and clearly executes a command function over the behavioral system” (Barren and Klein, 2016, p.4903).

The research work of neuroscientist Andrew Barron has also identified fine neural structures in the brains of honeybees. From his decade-long research, he believes that brain structures in this insect match the way the human midbrain processes spatial information (Anderson, 2019). Additionally, researchers concluded that “honeybees can learn and apply the concepts of greater than and less than to interpret a blank stimulus as representing the conceptual number of zero and place zero in relation to other numerical values. Bees thus perform at a level consistent with that of non-human primates by understanding that zero is lower than one” (Barren and Klein, 2016, p.4905) (Kaltenbach, 2019, p.72).

So, what level of insect consciousness can guide us in understanding how we can relate to them (Howard et al., 2018)? Is there a correlation between a higher knowledge of their subjective selves and a rise in empathy for them? These questions begin to help us define what is required to understand insects in order to promote change in our behavior towards them. We now know that when an insect is identified as a key agent in a system that benefits the welfare of humans, a great deal of public momentum is created to motivate government legislators to act, demonstrated five years ago when France banned several pesticides, some which were identified in bee colony collapses (Samuel, 2018).

Can domestication play a role in providing empathy for insects? Clues to this question can be found in Japanese historical texts that provide a highly imaginative, Animistic/Shinto and Buddhist perspective on their lived experience and value to humans (Hearn, 2015). These texts provide an aestheticized appreciation for these animals as it relates to their ability to conjure and amplify ambient conditions such as auditory mnemonics and ancestral worship. Two books provide insight into that history, Lafcadio Hearn’s 1921 book Insect Literature and Kanoh Yasutsugu’s 2011 book Singing Insect Cultural History: Known Places of Singing Insects and Insect Sellers.

Both Hearn and Kano describe the consumer market of singing insects in Japan from the 18th through the early 20th century. Hearn provides a chapter dedicated to discussing the history of selling a variety of chirping insects as musical pets (Hearn, 2015, p.129-156). His historical accounts were based on records available to him in Japan at that time, which allowed him to create detailed descriptions of the vendors and how their lives centered on selling and enjoying these insects. The wealth of information Hearn provides creates a framework for understanding how the cultural value of these animals was commercially shaped and measured at that time. Hearn’s description brings to life the beauty and magic of the role singing insects had in the lives of people in Japan (Kaltenbach, 2019, p.65). Having his account of the organized commercial activity of selling insects for no other reason than the auditory aesthetic value provides important historical legitimacy to the work of Oka, Kobayashi and Kaltenbach.

The usefulness of the products that bees, crickets, and silkworms produce has provided empathy for these animals during different periods in time (Kaltenbach, 2019, p.65). However, what happens when insects themselves become the commodity, as seen in the rise of entomophagy, insect as food? As an important alternative to industrial food animal production, do vegans consider them worthy of advocacy?

Cautionary Tale on Ethics: Insect Protein vs. Vegan Strategy

What standard of ethics should be applied to the use of insects? Since the 2013 United Nations report (van Huis, 2013) on the value of edible insects as an environmentally sustainable alternative to other livestock sources, a range of claims have been made on the relatively small footprint of resources required to produce this food source, especially as it pertains to greenhouse gas emissions, agricultural land,

and freshwater use. With mounting concerns over the future of global food stability and access to drinkable water, one might think this would be a welcome alternative; however, for those who are vegans, their socio-environmental stance is driven by an unwavering "morality of consumers to eat what is ethical," (Emel and Neo, 2015, p.237) applied to all animals, including insects.

Anecdotal evidence of the sternness of this moral position, was recently collected at a sustainability product exhibition/trade show in Tokyo. In December 2019, Kaltenbach exhibited a section of a prototype insect terrarium wall system. This installation proposed the raising and harvesting of crickets for use in food production within small terrariums nested in the cavities of a specially designed brick he had designed.

Figure 1. (left) Christopher Mark Kaltenbach explaining the Acheta Socket Brick + Terrarium wall system at the JIDA (Japan Industrial Design Association) Next Eco Design exhibition at Tokyo Big Sight, in Tokyo. December 5th to 7th, 2019. (right) Acheta Socket Brick + Terrarium wall system design by Christopher Mark Kaltenbach. photos: Miki Chishaki.

At some point during the event, an older gentleman approached him and questioned his use of insects as a food source. The gentleman accused Kaltenbach of demonstrating a complete disregard for these animals. While trying to explain the environmental benefits of raising this rich protein source over that of other industrialized food sources, he admonished him, declaring that no animal should be subjected to industrialized methods. Kaltenbach continued by pointing out the Japanese had had a long history, up until the early 20th century, of eating insects. Regardless of this historical precedent, the vegan advocate believed it to be a moral crime to breed crickets for human use and consumption. There appeared to be no environmental argument that could be offered as a defense that would change this individual's mind. In his eyes, the gravity of Kaltenbach's offense was tantamount to a mortal sin.

This tense encounter represented a vegan strategy of advocacy, where no level of litigation could penetrate the singularity of reasoning, "to abolish animal food production altogether and to cease consumption of animals" (Mcelwain, 2009, p.292). Kaltenbach's approach in presenting an ecological alternative was a desire for a "gradual reform in animal food production methods" (Mcelwain, 2009, p.292) away from beef, pork, poultry, and fish via the promotion of insect consumption. The display of the decorative terrarium wall system, as an expression of this philanthropic overture, was not environmentally progressive enough for the vegan. Proving the adage that forms a cautionary reminder to those who attempt to solve a societal problem with design, whether it be at an individual, community, civic, national, or global scale, "it should be remembered that one person's problem is another's home or fight for freedom or means of transport" (Davies and Parrinder, 2010, p.17). In the case of this cautionary tale, the need to promote an environmentally sustainable food source alternative was another person's moral offense.

Should this unwavering empathy displayed by the vegan advocate be championed? Should this ethical position be extended to other types of animal use, such as wildlife management" (Lunney, 2012) or the veterinary profession (Sandøe et al., 2003)? What about the use of insects in commercial industries beyond food manufacturing, such as in bioengineering and pet breeding? If insects can be promoted for use of their molecules or natural compounds such as amino acids, iridoids, or chitin, which help to wean society off the dependency on petro-chemicals or the overuse of soil and water, by its very nature, isn't this positive, pro-environmental activism?

In this section, three approaches to understanding and appreciating insects, at a deeper level, has been presented: the concepts of empathy, consciousness, and ethics, as it pertains to these animals. The pathway to a deeper value of insects, either through empathy felt towards them, or a scientific grasp of their level of consciousness, or applying a moral principle, all provide a way to construct a personalized belief system on how best to use and conceive of them. But do these concepts describe how to treat them humanely? What standards are applied? Does publicly treating insects humanely automatically equate to motivating pro-environmental advocacy? How does one ensure that an audience can be appeased? Currently, it is difficult to assess where exactly the moral high ground is when using these animals. For a dancer or designer to include and engage with insects in the public realm, it must be acknowledged that no matter what the best intentions are, misunderstanding and misperception are bound to arise.

3. Observational and Experiential Processes: An Emergent Behavioral-Model

> "[S]hifts in perception and positioning that can be provoked when we commit to more expansive ways of being in and of the world. That means looking more closely and listening more deeply, noticing fine details and attuning to processes, and at the same time adopting a wider, more holistic view that situates our experiences with larger webs of relationships, spaces and times." (Almarcegui et al., 2021, p.15)

Since Aristotle's *History of Animals*, it has been known that the pathway to understanding the natural world has been through reflective observation, be it the naturalist or the artist. The concentrated, documentable focus on the behavior, physical characteristics, and growth of animals and plants during extended periods of time and across seasons, defines the approach to fieldwork in the life sciences, and in creating scientific illustrations. This engagement with biological models became the basis for taxonomical, morphological, and ornamental motif studies, which today are important parallel lineages to the empirical and phenomenological studies found in design across several disciplines.

Beyond the Goethean Method: The Phenomenology of Insect Life

When it comes to understanding the techniques of observing natural phenomena and then translating this into an artistic response, the Goethean method is often cited (Verma, S.K., Punekar, R.M., 2019; Rowland, 2000). In basic terms, it is a four-step process: use, understand, become and channel. First, use all of one's senses to directly observe the phenomena in an objective manner; second, understand the phenomena over time; third, to become open to a new understanding and locate a suitable medium from which to express this; fourth is to channel that knowledge into an appropriate form to express those biological phenomena. We can see the graphic transference of an eye-mind-hand-tool activity that Johann Wolfgang Goethe (1749-1832) intimated in his writings and depicted in the antiquated scientific illustrations from the period. Today, designers have a canon of twentieth century urban observation work by which to be inspired. Annotated sketches, diagrams, and photographs as seen in Wajiro Kon's Modernology, and Terunobu Fujimori's The Street Observation Society or the détoumement (diversion) and dérive (drift) of Guy Debord's Situationist International (McLaughlin and Fry, 2001), all provide analysis tool kits for eye-witnessing the world in the most urban manner, if at times, a caterpillar's pace.

The usefulness of reflective observation for a designer is to activate the imagination towards an act of creative inspiration. However, when it comes to directing the designer's focus on a biological entity this can be bewildering, due to an expertise in people-centered analysis. Here, the references and cues are of another dimension and scale. For this activity, insects are especially appropriate biological subjects because of their small size, unfamiliarity, and the general bewilderment they can generate due to their foreign, non-mammalian characteristics.

When considering the work of Oka, Kobayashi and Kaltenbach, Goethe's method appears to be broadening with a necessity to add an additional step. In a way, it is a return to the first step; however, moving past simple empiricism into a subjective realm of sensorial interaction with the specimen. These works make the process-of-discovery mode of investigation itself the framed experiential work in a duration of intervening. However stylized—partially preconceived and/or aided with an object/environment—the form that is expressed is the human behavior set in motion to counter, join or contemplate the actions of the animal. This is an important distinction; in that it describes an intervention with the specimen from which to gain an experience that in turn coaxes a new behavior from the person. It is through this behavior that then a new understanding of themselves in relation to the insect is gained — an experiential subjectivity that generates a sense of empathy for the animal. The ability to observe this in another person or to be placed in a situation from which to gain this first-hand experience is the emergence of a biology-inspired performance process and the apprehension of a behavioral-model.

Catching Crickets

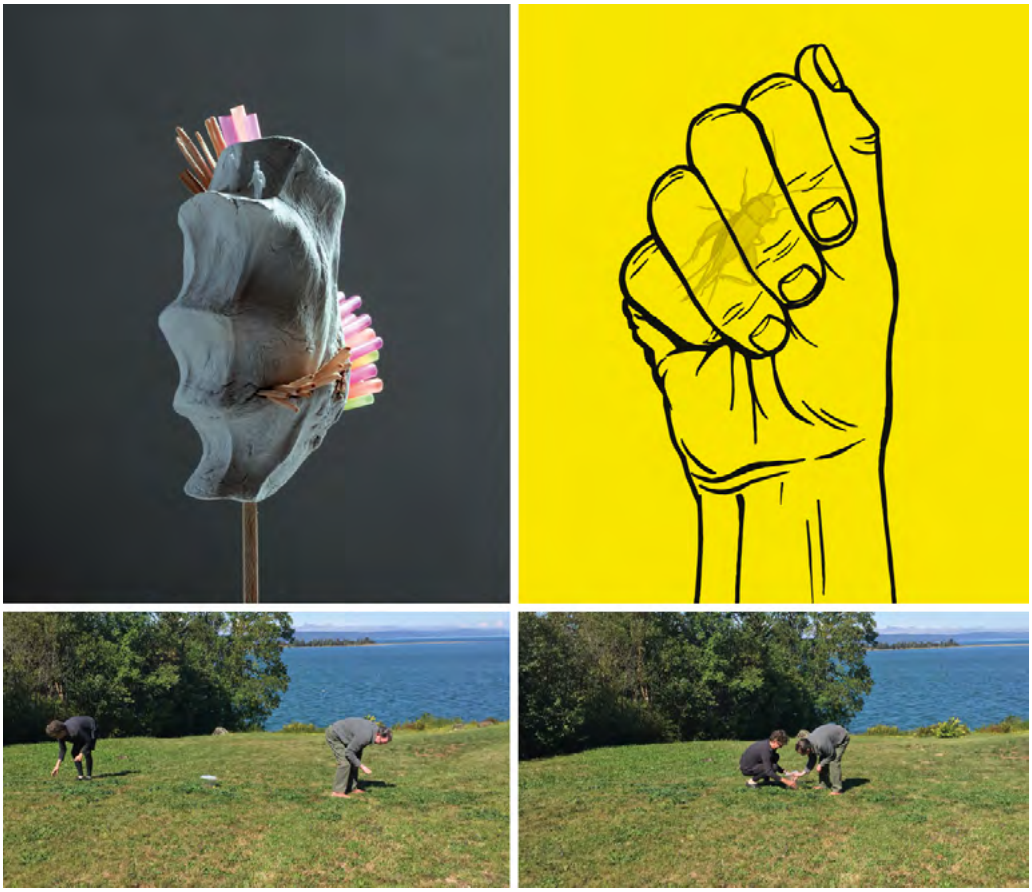

Figure 2. (top left) A small sculpture by Christopher Mark Kaltenbach representing the enclosed space of the hand occupied by a cricket, photo: Christopher Mark Kaltenbach; (top right) An illustration by Christopher Mark Kaltenbach depicting the cricket contained in the hand; (bottom left, right) Catching crickets, Christopher Mark Kaltenbach with architectural historian Dr. Christopher Mead in Smiths Cove, Nova Scotia, Canada. August, 2017. photos: Michele Penhall.

In Kaltenbach's PhD dissertation, he discusses coming upon a new appreciation of the minutiae of personal experience that insects provide. Like Goethe he learns that this requires a different mode of curiosity for which to become attuned to a distinct sensibility and that every encounter is an opportunity of possible discovery, even if not recognized at that instant.

An example of this shift in perceiving an insect in a new way is recounted by Kaltenbach, in an episode that took place in late summer of 2017. While assisting a colleague with excavation work, he noticed that in certain patches of the ground, black crickets were in abundance, at almost infestation levels. As he was preparing to teach a new design course on the theme of the insect order Orthoptera, to which crickets belong, he planned to provide students with their own crickets to care for, purchased from a local pet store. At that moment he recognized that caught crickets would be a good alternative, so he set out to catch them.

Using only his hand, he developed a technique for catching and holding the insect while transferring it to a terrarium. The technique is the forming of a perfectly enclosed pocket in the interior space of the hand—four drawn back fingers, curled against the base of the thumb and hand, and capped with the tip of the thumb.

Despite a few insects killed or maimed in the process, he eventually mastered this technique. The enthusiasm of this new-found activity even motivated a colleague to try the technique and join in the hunt, as he too had never caught crickets; the novelty of the activity was contagious.

After being swept up in the challenge of catching these insects and trying to form the perfectly enclosed pocket in his hand, he recognized something extraordinary. In the process of handling the crickets, he became aware of a new perception of the animal, an intimate connection that had nothing to do with what it looked like or what it could be used for. The insect was inhabiting his body and mind. He could feel the insect in the cavity of his clasped hand, the slight tickling of its legs on his skin created a mental world of a thing that was both real and imaginary. In the process of transporting it to a container, he also had found a new empathy and concern for its care. He had become attuned to the insect and with this engagement, a different persona was brought forth.

What had seemed at the time as a natural, pragmatic response to the necessity to catch crickets revealed itself as a theatrical activity; it had entertained those who watched the entire cricket-catching episode unfold. It was here that his interest in the performative possibilities of design was reinforced. The insect had created an invented engagement that no commercial application or historical precedent could have prepared him to anticipate. (Kaltenbach, 2019, p.74-75)

The observational and experiential processes of understanding an insect in this section of the paper demonstrate avenues for interpreting and feeling insect-empathy, -ethics, and -consciousness.
While these empirical activities of acquiring insect knowledge are understandable and replicable, how to reflect on these processes and the specimens themselves so it can manifest into creative work, such as a dance or product design, is beyond the scope of this paper. While the two speculative works described in the next section of this paper are void of clarifying what actual processes were used to determine their generation —serving primarily to provide examples of IX design—the proposed expansion of Goethe's method and description of Kaltenbach's technique for holding insects in one's hand has provided an opportunity to consider, through reverse engineering, their possible processes of ideation.

4. Interspecies–Interaction (IX) Design: A New Discipline

The neologism interspecies-interaction (IX) design borrows from the widely-used term user-experience design, also known as UX design. This term has gained popularity in the last twenty-five years due largely to the 2006 book Designing Interactions by Bill Moggridge, which chronicled the development of the personal computer, its software and user interfaces, as well as Moggridge's own career evolution from British product designer to a Silicon Valley, screen-based interface proselytizer. It is within the history of the birth and development of this consumer-electronic tool that a range of invented, pragmatic, engineer-based

development processes concerned with user testing were described, such as guided fantasy, participatory design, and blank screen experiment. Thanks to the proliferation of the smartphone app design industry, spawned by Apple's 2006 iPhone, user-experience design has come to signify those who work in app, website, display and/or service design, and more recently, even taking on an ethical dimension for those who wish to signal a populous, lowbrow affinity.

User experience has played key roles in architecture, product, print, package and wayfinding design for decades prior to the advent of the personal computer or smartphone — the Remington No. 1, 1876 (first mechanical typewriter), Open Air School (Amsterdam, Netherlands), 1927 by Jan Duiker, Animal car park pictograms for the 1967 Montreal World Expo by Burton Kramer, and Enzo Mari's 1974 Autoprogettazione line of furniture, just to name a handful. With the inane insistence to classify something so historically ubiquitous into a narrow field of digital application, it serves to reason that a case can be made for a similar narrow classification for designing, that which takes place between humans and animals, interspecies-interaction (IX) design. As mentioned before, the following two prototypes, both created within the last ten years, represent IX design as it pertains to insects, the documentary films titled Mao Moth Laos by Tokuro Oka and Mao Kobayashi, and the tool called Insect Viewing Apparatus (IVA) by Christopher Mark Kaltenbach.

Mao Moth Laos

Figure 3. One of the two documentary films by Tokura Oka, "Mao Moth Laos, Mao Kobayashi." Film projection at the "Insects: Models for Design" exhibition at 21_21 Design Sight, Tokyo, Japan, in 2019. photo: C.M. Kaltenbach.

Oka's films focus on evenings with the break-dancer, choreographer and amateur entomologist Mao Kobayashi. The presentation of the two films were in the exhibition *Insects: Models for Design*, curated by Japanese designer Taku Satoh for the Tokyo venue 21_21 Design Sight, in 2019. Kobayashi who at the time lived in the village Pukun, about an eight-hour drive from the Laos' capital Vientiane, was conducting field research on live *Lepidoptera* specimens and developing new breakdancing choreography. These activities were captured by the camera work of Tokuro Oka, a filmmaker, documentarian and cinematographer based in Japan.

Filmed with a stationary camera, we are witness to two narratives with views of nocturnal scenes of flying moths; at times outside on a porch or in an empty room with a single bulb and swarming moths; the other film with Kobayashi in the act of impromptu choreography within the vortex of moths circling a bare incandescent lightbulb. This documentary footage was projected on two walls in an intimate gallery space within the large gallery complex of the Tadao Ando designed, subterranean building. The two films were like facing pages in a book spread: verso, a record of the moths themselves; recto, Kobayashi in their midst.

Figure 4. (left) Exhibition poster "Insects: Models for Design," designed by Tomohiro Okazaki. The exhibition was held at 21_21 Design Sight, Tokyo, Japan, in 2019. (right) Japanese designer, Taku Satoh being interviewed by Christopher Mark Kaltenbach, July 26, 2019, at Satoh's office, Ginza, Tokyo.

Oka captures the spiral torrent of winged insects circling the bulb at various heights as if contained in an imperceptible cylinder extending down from the ceiling. These rare views, taken within rustic domestic interiors and void of most furniture, allow the single figure of Kobayashi, clothed and barefoot, to be centrally composed in the whirling, feathery, aggregate-permeated-dervish of hemolymph propulsion. As a break-dancer, he flails his body in spiral movements, no longer an isolated mass of self-expression, he becomes a symbiotic instrument, improvisationally responding, merging, and physically commenting on these animals' frantic flights.

Kobayashi employs a wide range of acrobatic moves: "the windmill, coffee grinder, kick slide step, three step, knee drop, kick out," (Hec 2023), at times appearing to be inspired by martial arts. The angular velocity and momentum control he maintains within the stylistic sequences of moves, interplays with the swirling moths, providing moments in which one does not know if the dancer is propelling the animals or vice versa.

The natural behavioral phenomena found in these insects does not have a singular explanation. It is reported that the cause of this "flight-to-light behavior" in moths appears to have several theories, one being the *light-compass theory*, it "postulates that moths navigate by flying at a constant angle to a distant light source such as the moon. When near a lamp, they mistake the lamp for the distant light source and fly at a constant angle to it. This directs them along flight paths that spiral in toward the lamp or circle around it (Baker and Sadovy, 1978)." Another theory is the *mach band*, which "postulates that artificial light produces visual artifacts of apparent darkness next to the light source. The moth flies toward the apparent darkness, which directs it into a path around the light (Hsiao 1972)." (Rich and Longcore, 2006, p.308) Ultimately, Oka's films provide glimpses into an impromptu, practice dance session by Kobayashi. This is a type of prototype performance in which his breakdancing moves are attempted. While the opportunity to peer into the process of choreography is in itself unusual, the true uniqueness of this footage lies in the incandescent summoning of a wide range of insects. It is within that moment and the overall spontaneity of the insects' interactions with the bulb and in turn Kobayashi's interaction with the insects, that we are provided a chance encounter that inspires awe in us.

Insect Viewing Apparatus

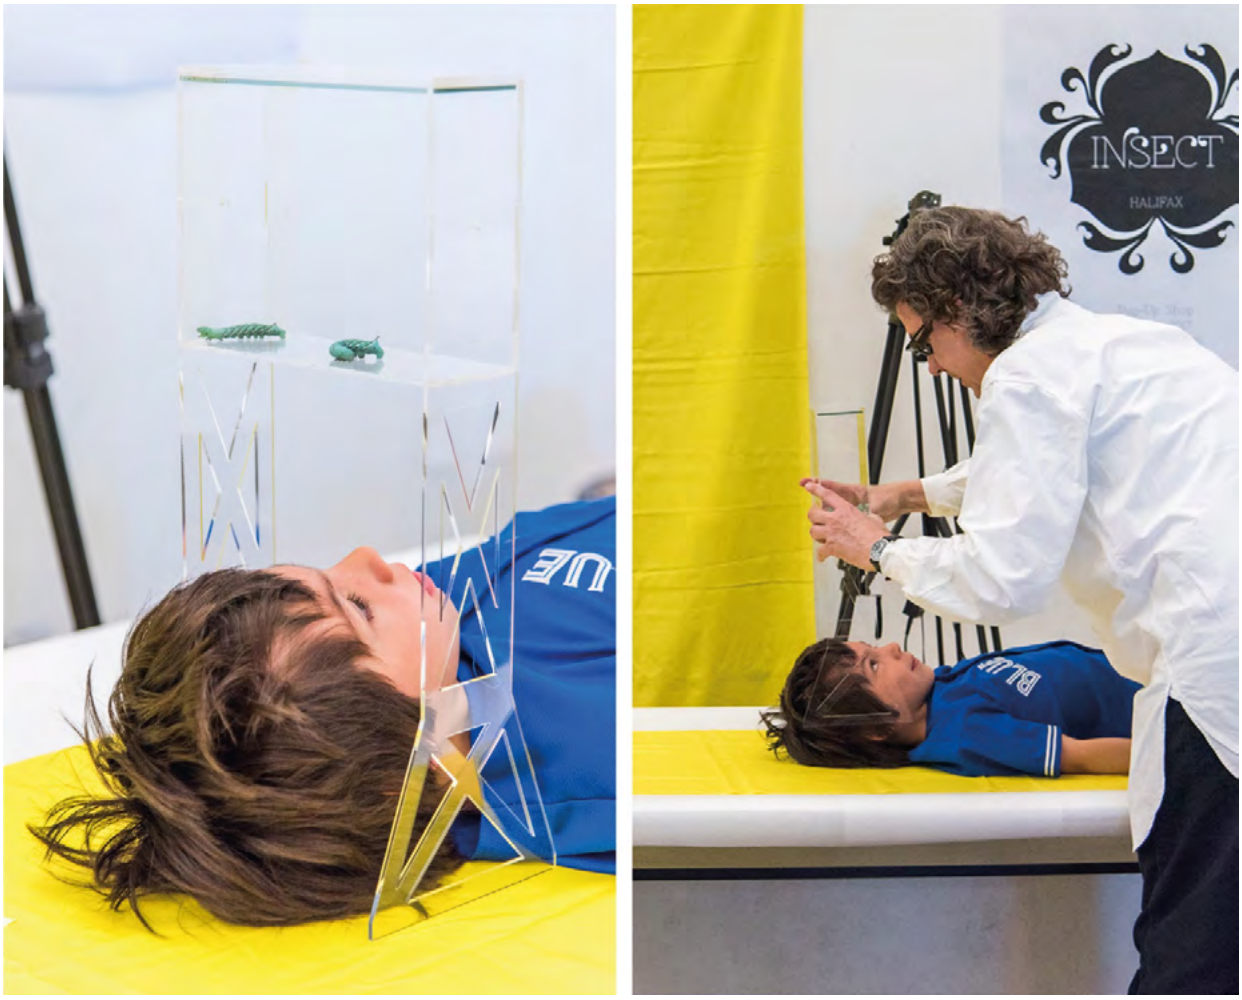

Figure 5. (left) Insect Viewing Apparatus (IVA) with Manduca sexta, blue hornworm by Christopher Mark Kaltenbach; (right) The IVA being placed over the head of a young participant in the Halifax Insect Pop-Up Shop by Christopher Mark Kaltenbach, May 13, 2017. The Shop was in NSCAD University's Port Campus, in Halifax, Nova Scotia, Canada during a community event. photos: Katherine Nakaska.

The Insect Viewing Apparatus (IVA) is a prototype tool for viewing insects created in 2016 by Kaltenbach. In the same year, it was showcased in two pop-up shops that he had also created. These shops, the first launched in Tokyo, Japan and the other in Halifax, Canada, focused on publicizing the commercial applications of insects. The IVA was created to explore how to change the power dynamic of the human-

insect relationship. In this design provocation, the objective was to reverse that relationship while keeping both the person and insect safe. Rather than looking down and examining insects, as is typically done, the device provides a view from underneath the insect. Within the two pop-up shops, a broad cultural and age visitor demographic were introduced to this apparatus.

This unprecedented view of an insect offered by this tool is constructed entirely of a transparent acrylic, the design being a basic box-carriage connected to two legs, with a mirror fixed underneath the carriage's lid. This important feature provides the participants with three simultaneous views: a view of the underside of an insect, a view of the top of the insect, and a view of the participant's own eyes juxtaposed with the entire insect. With the presentation of these three views into a single scene, the device sought to awaken the user to a different understanding of the insect.

Furthermore, the tool was situated within a type of scripted performance repeated for each participant, which dictated a specific mode of engaging the public and delivering the apparatus and insect to the visitor of the shop. Framed by an insect operator persona that Kaltenbach invented and performed himself, a formal manner of care for both the participant and the insect, positively elevated the experiential impact on the visitor. This created a kind of clinical atmosphere from which the public became compliant with the directions given to them in this physically vulnerable situation (Kaltenbach, 2019, p.118-141).

Here Kaltenbach describes the operation procedure of the IVA:

> "The activity began by offering to the visitor a choice of insect to be viewed. Once the insect was chosen, the visitor was asked to remove any excess clothing, guided to the edge of the table, and invited to sit down. If the participant was a child, they were asked if they would like to be picked up. While it was not necessary for the participant to take off their shoes, they were encouraged to if they felt inclined. Once seated, they were told to slowly lean back. The operator continued to try to put the participant at ease, usually placing his hand on their back to gently guide them back onto the table, moving his hand to the back of the head right before it touched the surface. Their legs remained dangling over the edge of the table. Asked if comfortable, they were requested to remain patient while an insect was placed in the apparatus. Once the insect was carefully positioned, the apparatus was then carried to the waiting participant and slowly lowered over the face, aligning the bottom of the insect carriage with the visitor's eyes. They were asked again if they were comfortable and reminded them not to touch the apparatus. Every 20 to 30 seconds, they were checked if they would like to stop the activity. Once they affirmed they would like to stop, the apparatus was removed, and they were told to wait until the operator returned to assist them off the table. The apparatus was then placed back on the adjacent table where other insects were kept. The participant was assisted off the table, and the insect was then removed from the apparatus and returned to its terrarium." (Kaltenbach, 2019, p.144)

In both shops, a therapeutic resonance in the apparatus-shop environment was inferred based on the reactions of the participants. The requirement of the participant to lie down and relax their body on the surface of a table, then to focus on both the insect and themselves in the apparatus enhanced a perceptual and psychological immersion into the insect experience (Kaltenbach, 2019, p.147).

Like Kobayashi's prototype dance performance, individuals are placed in their own unrehearsed engagement with insects where the spontaneity of the moment reveals something new about the animal, and more importantly about how that individual reacts.

5. Conclusion: Expanding the Definition of Design Applied Environmental Entomology

In this paper, a new mode of speculative, biology-based making and thinking has been defined, interspecies-interaction (IX) design, as well as introducing observational and experiential processes that expand the Goethean method. This research provides choreographers and designers examples of how living biological entities can be integrated into performative works. While the paper is solely focused on two disciplines and the use of insects, it can be expected that this design discipline provides opportunities for cultural producers working in any medium to create meaningful and aesthetically enriching interactions with a wide range of animals.

The broad domain of research being carried out on the empathy, ethics, and consciousness of animals, provides important and necessary avenues for gathering scientific facts and subjective interpretations of the inner life of an insect. However, these often support contemporary social structures and worldview trends that direct readers on how one should think and feel about these animals, rather than offering paths to explore and interact with them in ways that are meaningful and informative to that individual.

The necessity for public demonstrations of enthusiasm, care, and value for insects aims to increase both the desire for empathy and greater knowledge about them, which is also the central mandate for a zoos' menagerie. One may ask, what then is the choreographer and designer's broader conservation or pro-environmental objectives? And shouldn't those be made explicit? This is where a deviation from the zoological model is found, in that these works are created by individuals and not private, non-profit organizations, and therefore the scope of their mandate is modest. In addition, the nature of performance and design work aspires to be inspirational to some segment of society. Unlike the business of operating a zoo, which must have broad public appeal through the presentation of and education about the animals under their care, these IX design works wish to elevate the insects by enhancing or augmenting them. It is the hope that the experience of the work itself, conceived of by the choreographer or designer, will be the motivation for self-actuation towards pro-environmental action.

Furthermore, these works also represent an expansion and reevaluation of Christopher Mark Kaltenbach's dissertation and the insect-based design work contained in it, which he defined as Design Applied Environmental Entomology. While the Insect Viewing Apparatus (IVA) was originally developed under that objective, its application stood outside of the three commercial industries of insect bioengineering (Kaltenbach, 2015), food manufacturing, and pet breeding, which the dissertation identified as its scope of application (Kaltenbach, 2019, p.52-57). IX design is not concerned with the need to foreground insects' utilitarian function for the betterment of humankind, as a mode of deriving empathy for them and hence the need to protect them vis à vis pro-environmental activism. These works argue for an appreciation of these animals as they are, allowing for the insect's behavior to direct and in some instances co-create the aestheticized experience and presentation of them. Ultimately, the strength of Mao Moth Laos and IVA is in the use of what these animals naturally do: fly around a light bulb and crawl on surfaces, that we are left to reinterpret them, as they are, and to see them as if for the first time (thanks in part to being framed in artificial and highly aestheticized settings), and to find the wonder and joy in their simple, yet amazing physical expression.

About the Author:

Dr. C. M. Kaltenbach is an Associate Professor in the College of Architecture, Art and Design at the American University of Sharjah. He is a designer and writer who has worked in interdisciplinary roles in design and design education in Australia, Canada, Japan, Macau, United States and the U.A.E. The founding director of the interdisciplinary design studio actionfindcopypaste, clients include Japanese company's Sony, Kirin and Mitsubishi Jisho; the French company Aigle, and the University of New Mexico Art Museum (U.S.A.). He holds a U.S. patent for a 3-D printing vending machine concept. His 2019 Ph.D. degree in the School of Architecture and Urban Design at RMIT University launched a new practice focused on reframing the insect through design. His writing appears in the books "Insectum" published by NSCAD University, and "Stories from the Camera" published by UNM Press, as well as in the magazines FRAME and MARK and the Australian AR and INSIDE.

KEYWORDS | DE-ANTHROPOCENTRISATION, OBJECT NETWORKS, OCEAN FUTURES, DESIGN THEORY

ABSTRACT | The ocean can be seen as a hard-to-reach place for human empathy and tangible connection for inspiring behaviour changes to reduce climate change impacts. A healthy ocean is crucial for essential human activities ranging from transport, food, oxygen, CO2 absorption, recreation, and tourism. For a long time, designers have been engaged with designing for the ocean primarily through recreational and industrial equipment for fishing, tourism, transportation, and leisure. A new climate critical role for design is emerging which requires a strategic systems-based approach combined with more traditional design solutioning methods. We conducted a design research experiment using an AI sensor package installed on a ship to geolocate and identify objects across the Atlantic Ocean on a 6,070 nautical mile voyage between Kangerlussuaq in the Arctic Circle in Greenland and Poole in Dorset, UK. The motivation was to conduct a broad cross-sectional object identification scan using 4k cameras to capture 'everything that isn't the ocean' to begin connecting the intangible ocean for co-designing solutions. The focus of this research is to identify theories and concepts of object-network relations that go beyond anthropocentric concerns to include more diverse stakeholders and multi-species representation and communication in future design work. We draw on a range of theories from Actor Network Theory, Boundary Objects, Suffixscapes and Object Oriented Ontology to compare pre- and post-theorising with applied fieldwork to draw conclusions around liberating conceptual models. We conclude by discussing how we can enhance inclusive representation of 'others' into climate sensitive research and design driven decision-making processes.

1. Introduction

Designers often tackle ocean issues after encountering a problem via personal experience or reviewing secondary material. While this has many benefits it also risks diverting crucial effort away from the most critical areas. Tangible issues like ocean plastics impact are serious but they are also tangible, encouraging design solutions. Even more significant challenges like a 2^0C warming of the seas or the resilience challenge posed by cascading regime shifts (tipping points) (Rocha et al, 2018; McKay et al, 2022; OECD, 2022; Dietz, Rising, Stoerk, Wagner, 2012) impacting ocean systems, which are some of the most sensitive to change, are far more difficult to address. A new global role for design is emerging which requires a strategic systems-based approach combined with the more traditional design innovation solution methods. This opens the possibility of exploring the potential for behaviour change to support coastal communities to shift from vulnerabilities to enhanced adaptive capacity to cope with widely anticipated future coastal change. At the heart of this role shift lies a need to connect ocean science and data with communities who need to use evidence of how the ocean is changing to adapt to new practices and relations. In other words, there is a need to bridge the quantitative and qualitative data gap between evidence and action.

The [Redacted for review] is a long-term project awarded a UNESCO Ocean Decade (IOC,2021) implementing partnership status from 2023-2030. The core concept is to support developing new economic models for the ocean recognising that sustainability and regeneration have complex human and environmental connections. We decided to conduct an initial experimental survey that would go beyond 'design issue selection' and focus instead on data gathering. Our aims were to:

- Develop a design research experiment that could traverse the quantitative-qualitative data gap;
- Open the possibility of new ocean issues and new understandings to emerge;
- Use data visualisation techniques to make the ocean and its objects more tangible;
- Support a long-term strategic prioritisation of design effort;
- Focus on a broad definition of objects as potentially designable outcomes.

The experiment involved a broad cross-sectional object identification scan using four 4k AI cameras and a sensor package (Fig. 1 right) mounted on the monkey island of the St Helena ship (Fig. 1 left) to capture 'everything that isn't ocean' between Kangerlussuaq in the Arctic Circle in Greenland and Poole in Dorset UK via the Azores, Gibraltar, and Sardinia in Italy. The unusual voyage was away from shipping lanes, and once the AI sensor package and cameras were installed, data and recordings were made continuously throughout with the research team swapping drives in Sardinia (further details of the technology packages, quantitative data analysis and qualitative co-design work are reported in separate forthcoming publications).

Figure 1. The St Helena showing camera survey angles, the sensor package located in the radio room and camera shrouds located port and starboard on the monkey island handrail approx. 30m above the ocean.

Our methodology involved an initial critical review of potential object-network theories followed by a comparison and an exploration of combinations of models. We then conducted a pre-and post-engagement analysis to reflect on how the theories might influence our understanding and shaping of ocean-object network relations on the transatlantic identification voyage. The influences could apply to a range of areas from participants' engagement planning and emergent methodology progression to technology selection and integration through to meta level approaches that inform more subtle types of decision making. We also speculated how our current understanding can enhance inclusion and representation of other xeno-species (Schmeer, 2019) into climate sensitive research and decision-making processes.

2. Ocean Object Network Relations

The aim of concentrating on objects is to consider how follow-on co-design interventions can be focussed on tangibility and how coastal communities can relate to these artifacts in terms of everyday lives, routines, and rituals, and how these objects can elicit narratives and physical, cultural, and psychological connections. One of the key challenges in this work is how to develop an understanding of the relations not only between humans and objects but also allow possibilities for other actors beyond the human sphere. These can range from objects, events, and living ecosystem animals, plants, and ocean life. The challenge was to find a conceptual model that supports us to make decisions on tools, methods, methodologies, and analysis processes that maintain a potential for the inclusion of the ‘other’ at future stages of the research. We also felt the need to question traditional design anthropocentric preferences in terms of what could be considered an object and move beyond objects as products and linked service and experience solutions to liberate new creative opportunities.

We developed an expanded notion of objects going beyond those made by humans and nature, and used a shorthand description of things that could be perceived as ‘moving against the background’ to provide more co-researching narrative power allowing co-design processes to move beyond more traditional object orientated problem solving. Apart from the human tangibility of objects there also exists the potential of intra-object relations. These were important considerations to drive decision making and visualisation design in a 3-dimension geolocation platform that we could use with participants.

While there exists design literature exploring what might be broadly termed as ‘de-anthropocentrisation’ there remain few examples testing or comparing theories in practice beyond speculative works and even fewer that test out large-scale explorative data gathering away from land-based environments. We use the slightly awkward term de-anthropocentrisation here to deliberately indicate the desire to shift away from human-centred decision making in complex systems (climate change) as opposed to the broader interests of post-humanism which has wider concerns. Earlier work by the Authors (2021) has highlighted the need to de-anthropocentrise healthcare environments and the need to invert the position of human-centred design in the value pyramid (Authors, 2021, p.5). In the context of this research a powerful need emerged to review several theories that could underpin our experiments and provide opportunity and capacity for future work aiming to reduce anthropogenic privileges. The space between de-anthropocentrising theories and the practices of design contain confusions and contentions and it is not our intention to solve these, only to illuminate where possible our experiences of them.

3. De-Anthropocentrising Theory

We considered a range of object-network theories. There are no methodologies we have found that prescribe which theories should be considered or in which combination and we have therefore used a variety, some of which the researchers have experience of using in previous fieldwork and others only on a theoretical level. Some of the theories we have selected are clearly part of much larger philosophical movements while others are more discrete in scale. This is important as we recognise that the terms theory, concepts, and philosophy have varied usage across the sources we have reviewed.

A prime candidate for consideration is Actor Network Theory (ANT), a material semiotic theory originally developed by Bruno Latour (2005), Callon, Law and others to remove human-centred priorities in network relations to allow new types of power structures to emerge from elements that have traditionally been excluded or marginalised. Non-human actors can drive change and gain power in social scenarios. Actors (or actants) are anything that has the power to apply change communicated by a mediator to other actors. The power is derived from how new power (politics) emerges from the network. However, there are several contentions with ANT. The definition of what is an actor, and an intermediary (mediator) is inconsistent following research by Toenneson et al (2006) who reviewed material from seventeen ANT journals finding differences in "material," and the attribution of authorship and responsibility. The impartiality of actor networks has been questioned by Mutch (2002), and Collins and Yearley (1992) highlighting one of the key limitations of non-human liberation governed by human networking efforts. Latour and others have resisted turning ANT into a technology-driven networking effort although many examples have since been created including healthcare technology (Cresswell, Worth and Sheikh, 2010), online community participation (Rivera and Cox, 2016), and development informatics (Faik, Thompson, Walsham, 2013). Revisiting ANT Latour has claimed that it is "a powerful tool to destroy spheres and domains… Yet it is an extremely bad tool for differentiating associations" (Latour, 1996, p.380).

The issues of differentiating between actors and mediators can have significant impacts on where power relations lie but even more significantly in a design context can mean very different things can become visualised as 'objects' (actors) versus mediators and affect design issues emergence and follow on action.

Boundary objects (BO) are an extension of ANT developed by Star and Grisemer based on the study of Berkeley's Museum of Vertebrate Zoology collections. They set up the building blocks differentiating away from ANT with an opposite view of emergent boundary objects concentrating on conceptual variance with rich and thick descriptions. Star and Grisemer identify a series of 4 inter-related boundary objects including: repositories, ideal types, coincident boundaries, and standardised forms. The institutional value of boundary objects is further confirmed by Caccamo, Pittino and Tell (2023) who conducted a literature review of 87 sources finding that they are a multifaceted construct, integral to organisational life. The organising role can be a competitive advantage leading to organisation improvement uncovering how boundary objects are a fundamental part of the innovation process. Scoles (2018) in researching messy objects describes how boundary objects can strengthen the pursuit of ANT studies in continuing education. In studying the overlaps, Scoles recommends delimiting linear mediators and following the actors to find emergence. Boundary objects have emerged from a diverse range of contexts including contracts. Franco-Torresa, Rogers and Ugarellic, (2020) study the agency role of a city sustainability department and how it changed the urban concept of water flows. They explore water flows in city emergency events and identify some useful sub-concepts including pluralistic tolerance, selection pressure, social worlds (worldview) and objects as shared aims. The city's flood plan is identified as the boundary object and its impact on the collaboration of several agencies is reported. Closer to design research Comi and Vaara (2021) study political dynamics in knowledge work with a special focus on visual artifacts dealing with pragmatic boundaries. In the context of architectural practice, they conclude that visual artifacts can manipulate the boundaries of organisations with political impact.

In design research, Balint and Pangaro (2017) stretch the concept of boundary objects from the role of emergence in social sciences to a provocative probe in a design context. The use is inverted from a slowly emerging realisation to an object that transgresses boundaries and links to Scoles' use of the term messy objects. We therefore see potential for boundary objects as either emergent opportunities in networks to unleash new creative potential via divergent issue descriptions or via the Balint Pangaro approach of creating boundary objects with the specific purpose of probing new opportunities. Limitations for our purposes emerge from the higher degree of anthropogenic focus, particularly if traditional thick and rich descriptions are used and more emphasis is placed on actors as opposed to mediators due to the focus on an emergent common. This may have the effect of offering less xeno (different in origin, non-human) opportunity in the future unless a particular focus is applied.

Suffixscapes (Appadurai, 1990) derive from the field of global cultural anthropology with an aim to identify and explore disjunctions, or unequal flows of power across a series of thematic landscapes. Conversations and communication take place across a global series of landscapes or 'scapes' including the: Ideoscape (disseminating ideas), Ethnoscape (cultural movement of people), Technoscape (how machines facilitate impact), Mediascape (presenting and shaping of information and opinion) and the Financescape (rapid economic movement of money). Disjunctions provide pivotal points of focus showing how power is leveraged over different groups both within and across suffixscapes, national borders and continental boundaries. The aim is to bring forth new voices and make cases for reducing exploitative structures and institutions. The concept in hindsight can now be seen in the context of decolonisation and remains an under-utilised idea in this field. Modifications to suffixscapes include Bello's Goodscapes with a focus on objects (Bello, 2010), and examples of this theory exist in practice-based design research including translocated design by the Authors (2013; 2017) and Rassouli (2024) in the context of decolonising resource constrained innovation. Although unsurprisingly not mentioned in the literature (1990), suffixscapes focus entirely on human-centred concerns in power relations. This does not however preclude its use more widely to identify disjunctions between 'other' species, human and object relations in the context of climate issues. For example, the CETI initiative (2024) is devoting considerable resource to decoding whale speech to develop inter-species communication affording the future opportunity to bring other species into suffixscapes communications. In the case of whales, identifying disjunctions in human-ecosystem impact could prove very revealing. In Appadurai's later work we can gain significant value from the following statement that:

> "The primary problem with images of object agency, network and the device is not just that they tend to lose the soul of objects, in spite of their intentions to reanimate the object, but that they have no real grip on the deepest problem of objects, which is their capacity to generate contexts. The problem of contexts is one of the black holes of current social science, and this black hole opens new possibilities for thinking about design processes from a social and cultural point of view." (Appadurai, 2013, p.258)

The black hole highlights a major issue in the social sciences that is not dealt with in boundary objects, that objects emerge from context as human-driven interaction but tell us very little about the reverse, how objects make contexts. This is addressed in part by ANT and semiotic relationality "a network whose elements define and shape one another" (Law, 2007, p.7). The questions around objects and contexts reinforces our decision to focus on objects and how they can be significant creators of place, meaning and most importantly the capacity for difference and change.

In design terms capturing disjunctions through co-research and co-design processes could focus effort in more strategically valuable places with a thematic link to scapes highlighting design opportunities. While suffixscapes is conceptually weak in dealing directly with objects, work by Authors (2013; 2017) and Rassouli (2024) have shown that there is no issue with object inclusion as a research focus.

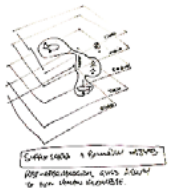
Object-orientated ontology (OOO pronounce triple 'O') emerged from the analytical branch of western philosophy sitting within speculative realism. It reacts against the history of human-centric ontology in philosophy and instead proposes an object orientated approach that flattens human value pyramids and creates places and spaces for emergence. It shares an affinity with some aspects of ANT and boundary objects but rejects the networking of ANT and the actor human-centred focus of boundary objects. Graham Harman (2018), Ian Bogost (2012), Levi R. Bryant and Timothy Morton (2013) amongst others have developed aspects of the philosophy which centres around a number of concepts including that all objects are created equally but some are more equal than others (Harman, 2018; Bogost, 2012), real objects and sensual objects that animate relations between real objects, and unit operations and carpentry (Bogost, 2012) referring to properties for intra-object relations and practices. Harman expends considerable effort in rejecting 'theories of everything' from physics criticising smallism (assuming that studying particles can explain all bigger structures and phenomena) causing undermining and overmining (claiming that emergence and large-scale observations are driving forces). The combined duomining integrates critical approaches that attack object-centred philosophies from both below and above. Criticism of physics

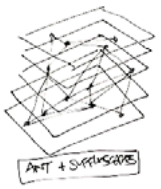
'theories of everything' can be summarised as theories of everything that physics is interested in, but not everything is interested in physics. An example used is religion and spirituality which string theory (the main contender as a science theory of everything (Becker, Becker and Schwartz, 2007)) is unable to explain (Harman, 2018). Religion and spirituality account for major parts of many peoples' lives and often drive huge geopolitical events yet is discounted as a subject for the theory of everything in physics. Harman, Bogost and others go to great lengths in exploring the nature of objects with Harman giving a useful example of the Dutch East India Company VOC as an object (Harman, 2016). The VOC has many properties of an object, but when we come to assess its components we find the ships, employees, offices, and practices are highly dispersed around the globe and cannot be seen as a traditional object in the Liebnitzian sense. Morton describes these as hyperobjects (2013). Wilde (2020) focusses on relationship issues in OOO arguing that there cannot be a hierarchy between objects and relations. This is particularly important following the OOO argument that an object cannot be summarised as the total of its external values. Furthermore, an argument is made that an object cannot be separated from where it is, aligning with Appadurai's claim that objects make contexts and the inability of current social science theory to explain how this takes place (the black hole). In a review of post-humanist theory including OOO, ANT, non-representational theory, feminist new materialism, and transhumanism Forlani (2017) argues that in the context of design research decolonial and critical race theory show that limitations of inclusion and empowerment can continue to exist in post-colonial theory. Attention is paid to OOO's flat ontology and the refusal to prioritise special interests.

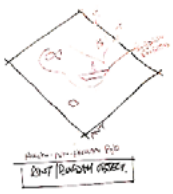
In applied design research Linley, Akmal and Colton (2020) report on a design research laboratory project developing IoT interactions. They focus on how advanced technologies such as AI and IoT challenge traditional concepts of reality and find that design research and philosophy (OOO) can develop partial answers and 'proxies for the unknowable' (Lindley, Colton, Akmal, 2018). The subject of their research provides scope for OOO to provide generative ideation and experimentation although these appear to be experiences of the researchers as opposed to participants. OOO has much to offer design research both in applicable designerly concepts such as real and sensual objects alongside practices such as carpentry. Its conceptual base in aesthetics engages well with both tangible and theoretical design practices and can have value in helping us understand the visualisation of objects and diverse relations.

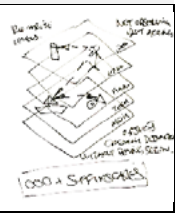
We are primarily interested in the conceptual power of these theories rather than their specific practices, for example rich and thick descriptions of boundary objects or highly complex network analysis of ANT, ethnography, or OOO.

4. Pre-Work Analysis









Based on the theories selected and reviewed in section 3, table 1 summarises the value of each of these across the criteria of research interest, project potential and assumed limitations to develop a foundation from which to gauge value. Our methodology in this respect is highly emergent (Gaver et al, 2022) and we place value on uncertainty (Gaver, Boucher and Pennington, 2005) in a constructivist epistemological position.

Table 1. Pre-data Gathering and Fieldwork Theory Analysis.

Theory	Research Interest	Project Potential	Assumed Limitations
Actor Network Theory (Latour)	Ability to trace relations and de-anthropocentrise emergence of new observations and flows.	Use visualisation applications to make actor networks between ocean and human activities and natural and human-produced objects.	Linearity of relations, punctuating the network, defining mediators and intermediaries, space for multi-stakeholder layered narratives?
Boundary Objects (Star & Grisemer)	Emergence of boundary objects in a hard-to-reach challenging environment with complex actor relations and diverse power relations.	Potential for descriptions of conceptual variance, delimiting design assumptions around designable or physical objects.	Sophistication and richness of network interactions at scale. Ability of design research to transgress BO criteria. Human centredness.
Object Orientated Ontology (Harman)	Landscape where human agency and visibility of objects ebbs and flows allowing new realisations with potential for ocean stakeholders to find unexpected relations.	Conceptual inspiration supporting practices and allowing space for de-anthopocentrised relations through to comparing carpentry etc. to design research practices.	Lack of applied design research and in particular OOO's relationship to network and concrete relations, actions and impacts across different human and non-humans.
Suffixscapes (Appadurai)	Layered landscapes allowing conversations on disjunctions in information flows with potential to support identifying ocean issues.	Possibility to add new novel 'Bioscape' layer to de-anthropocentrise suffixscapes and allow more direct spaces for non-human agency.	Networkability of the concept. Anthropocentric model based on human layers. Object focus for design actions?

Going beyond the conceptual value of the theories we have reviewed is an opportunity to consider combinations of theories and their geometric relationships. Table 2 captures combinations of OOO, ANT, Boundary Objects and Suffixscapes across 6 combination criteria. It explores potential relational spaces for design visualisation and conceptual richness. Note that orange highlights indicate potential issues with combinations.

Table 2. Geometric Ocean Object Network Combinations.

	Theory Combinations					
	Boundary Object + Suffixscapes	Boundary Object + OOO	ANT + Suffixscapes	ANT + Boundary Objects	OOO + ANT	OOO + Suffixscapes
Geometries						
Criteria						
1. Relationship between humans & nature via objects	Human and non-human object relations can be mapped, scope for networking?	Potential for OOO and BO to exist and connect outside of human view to nature.	Networking and scapes can combine via disjunctions.	Close bounded relationship with nature accessible.	Networking power and flat OOO allow nature links.	Through OOO clear links, scapes less so but possible.
2. Power to de-anthropocentrise	BO and scapes least powerful de-anthro combination.	OOO strong potential though some BO limitations.	Good via ANT though less when combined with scapes.	ANT good potential though less with BO actor focus.	Strong with both though conceptually different in aims.	Partially with OOO however, scapes less tested.
3. Connects quantitative to qualitative transfer	No limitation to quant/qual in scapes or BO literature.	Potential though not highlighted as a possibility.	Quant can be actors and scapes both quant/qual.	ANT via mediators, BO through thick and rich descript.	Via ANT good potential OOO less obvious.	Potential but may need additional methods.
4. Inclusive with future 'others' and stakeholders	Descriptively rich though less in other mediums.	Strong via OOO flatness BO good engagement.	Strong ANT less with scapes but has potential.	ANT good and qual depth of scapes supports.	OOO and ANT stakeholder linking potential.	OOO strong and scapes depth and disjunctions.
5. Tests de-anthropocentrised theories in practice	Scapes and BO's more anthro focused in practice.	OOO good potential but BO more human centred.	ANT good potential, scapes not intended for this.	ANT good potential and BO can provide qual depth.	Strong double potential but also opposites in some intentions.	OOO flat ontology designed for this but not scapes.
6. Participatory understanding of 'hard to reach' environments	Clear spatial relationships with scapes and BO practices.	BO and OOO both point towards this capacity.	ANT and scapes both have potential to connect.	BO and ANT have potential to deliver this aim well.	OOO applied concepts and ANT networking reach.	Scapes likely lead on this capacity to understand via practices.

Previous work by the Authors (2) found value in combining suffixscapes and ANT to discover how design process agency acted in a translocated making process across geographically distinct socio-spatial groups (Fig.2). We decided based on the object network geometrical analysis to consider OOO and Boundary Objects as our preferred conceptual candidates while leaving opportunity for Suffixscapes and ANT to play a role. OOO and BO provide a powerful combination of deanthropocentrising power with the boundary object depth, human and potentially inclusion of 'others' into design perspectives. OOO's special and expanded focus on objects is intriguing with potential to open up new co-design possibilities.

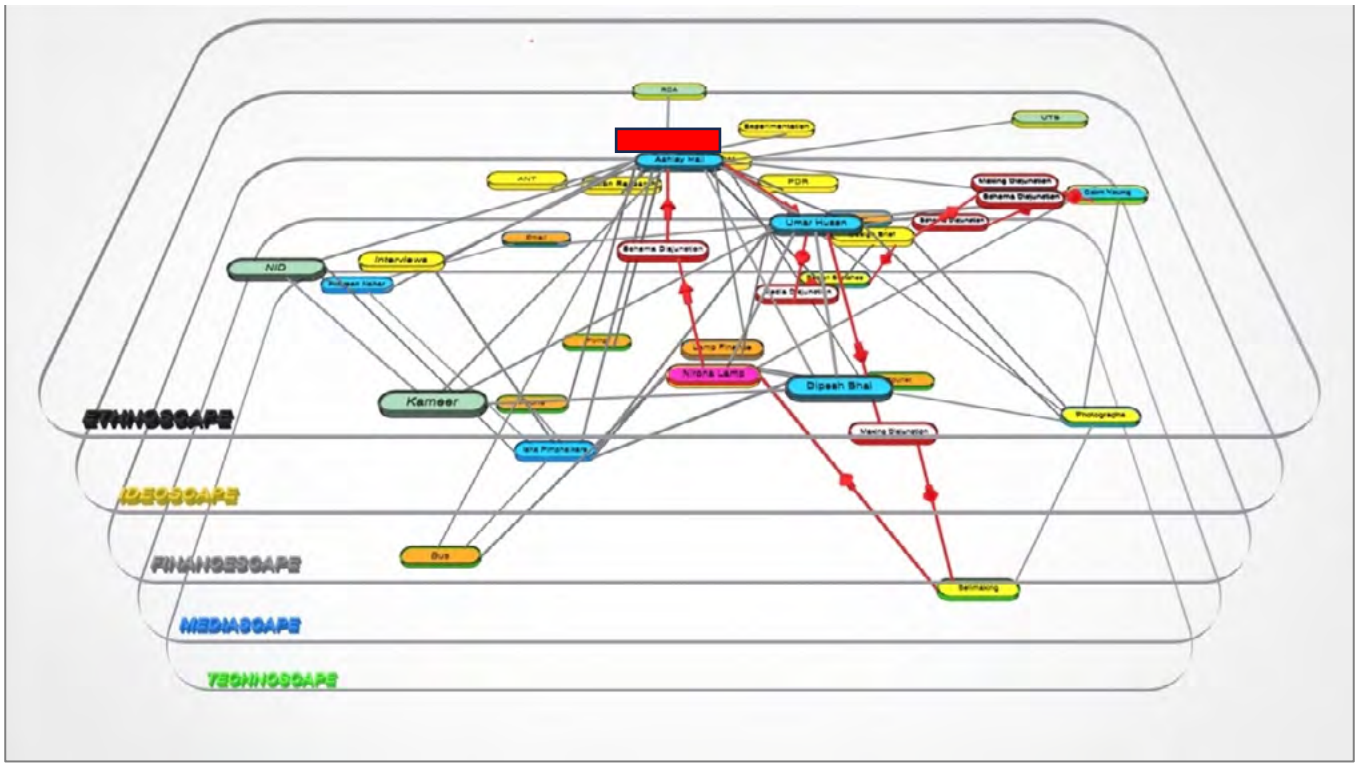


Figure 2. Combination of Suffixscapes and actor network showing role of design process in driving agency across geographies Authors (2017).

5. Post-Engagement Reflection

Data analysis via AI and a human observer using pomodoro technique (Cirillo, 2007) of the 12,140 nautical miles of 4k footage from the two wide-angle camera's on port and starboard identified 3,605 objects. We decided on different spatial categorisations of above, on, and below the ocean and human and naturally made objects.

An immediate issue was the definition of what is an object. Figure 3 shows a sample of the diversity of objects observed with some obvious examples including a seal (bottom right), dolphins (bottom centre), ships (centre and centre right), garbage (middle left), and then less certain objects. The top left shows a powerful tidal effect where the outgoing mineral-rich glacial till turning the water a strong light blue-green colour which moves quickly up the Kangerlussuaq fjord past the ship. We can also see in Figure 4 unexpectedly small objects on the left which are water and ice crystals forming on the camera lens at night and even more surprisingly on the right we see the tail end of the 500-mile-wide hurricane Larry – the largest storm in the north Atlantic for 10 years – which the ship sailed through. Our surprise with hurricane Larry was that the AI object identification (design for land-based use) was almost constantly on for several days indicated by a purple stripe on the right side of the footage (Fig. 5). It was only after thinking this through that we realised the complex sea state produced by the hurricane was interpreted by the AI as an object, one that was so big in fact that the ship sailed through the edge of it for several days. The hurricane was visible to the human observer as weather, but to our AI it was in effect a continuous object. We had not anticipated encountering any object at this scale let alone to sail through one. The glacial till tidal flow and hurricane may be conventionally recorded as effects rather than objects.

However, we wanted to ensure that all objects were treated equally as our research was experimentally emergent and we wanted to give future collaborators and participants equal access to all types of objects. This led us to realise that we had begun to apply OOO's more diverse arguments for what constituted an object, possibly even hyperobjects as described by Morton (2012). Hurricane Larry needed satellites, a ship, cameras, an AI sensor package, an internet connection, algorithms, visualisation software and human

observers to perceive its presence. In some ways this could be compared to Harman's (2016) description of the Dutch VOC having such diverse evidence of its objectness. We also recorded other effects ranging from pools of oxygenated water, sunsets, mirages, unexplainable shadows, and various slicks. Each of these was given equal status via its description, GPS location, image icon and short MP4 clip. Combining effects into objects also addresses Manuel De Landa's criticism of OOO (Harman, 2018, p.41) not being able to address effects. Our experience also agrees with Harman's definition of "OOO means 'object' in an unusually wide sense: an object is anything that cannot be entirely reduced either to the components of which it is made or to the effects it has on other things" (Harman, 2018, p.43).

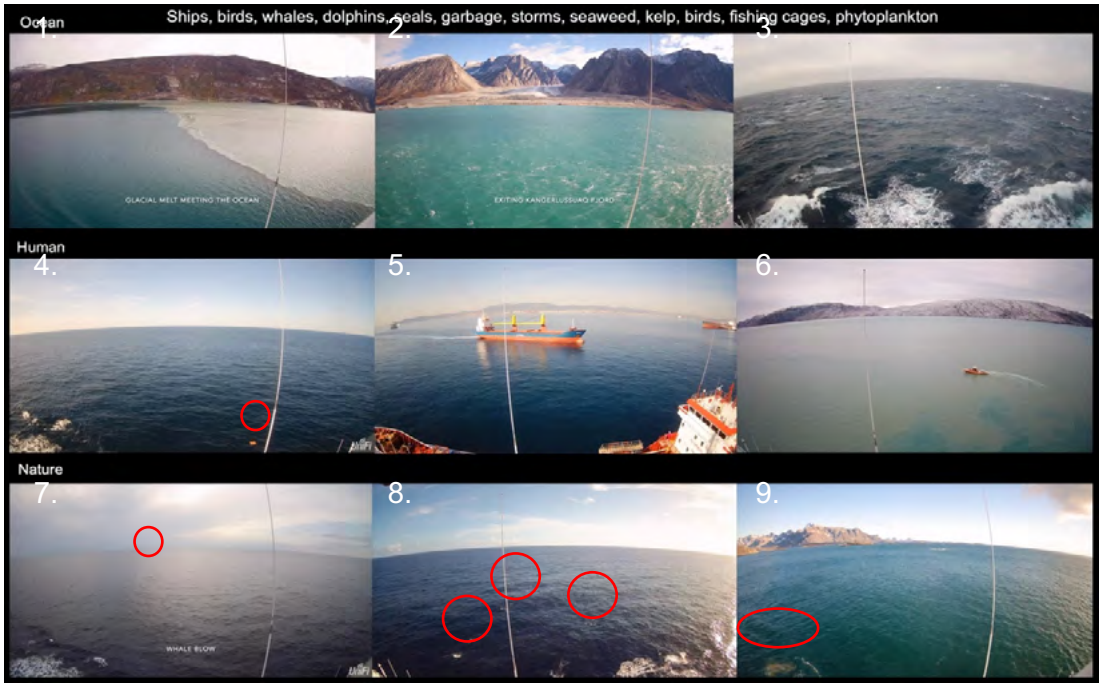

Figure 3. Diversity of ocean 'objects' identified by the sensor package from ocean effects on the boundaries of an object (1,2) through to natural; megafauna (whale, dolphins, seal; 7,8,9) to human made (5,6); waste (4), ships and aeroplanes.

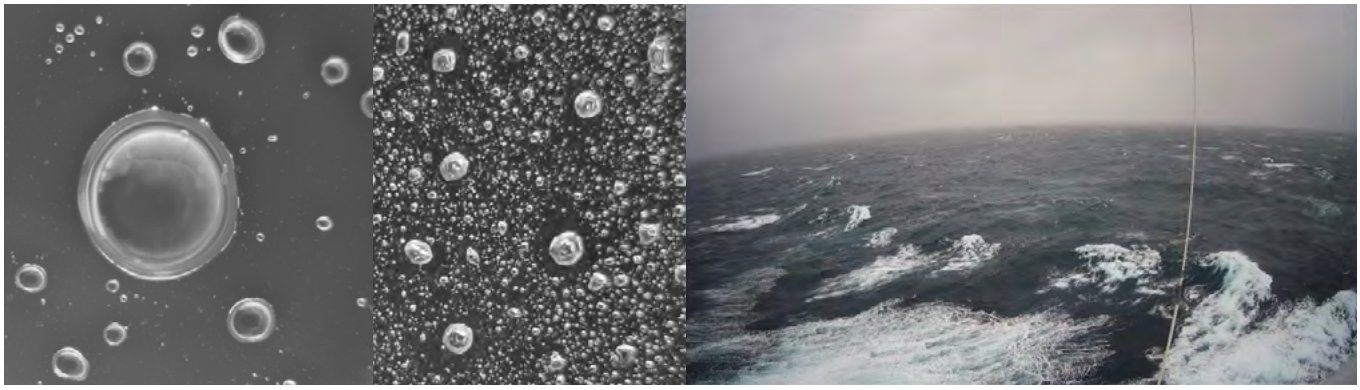

Figure 4. Objects observed vary in scale from water droplets and ice crystals 1-2mm (L) (note seascape inversion lens effect) directly on the camera lens up to the tail end of hurricane Larry around 500 miles wide that the ship sailed through (R).

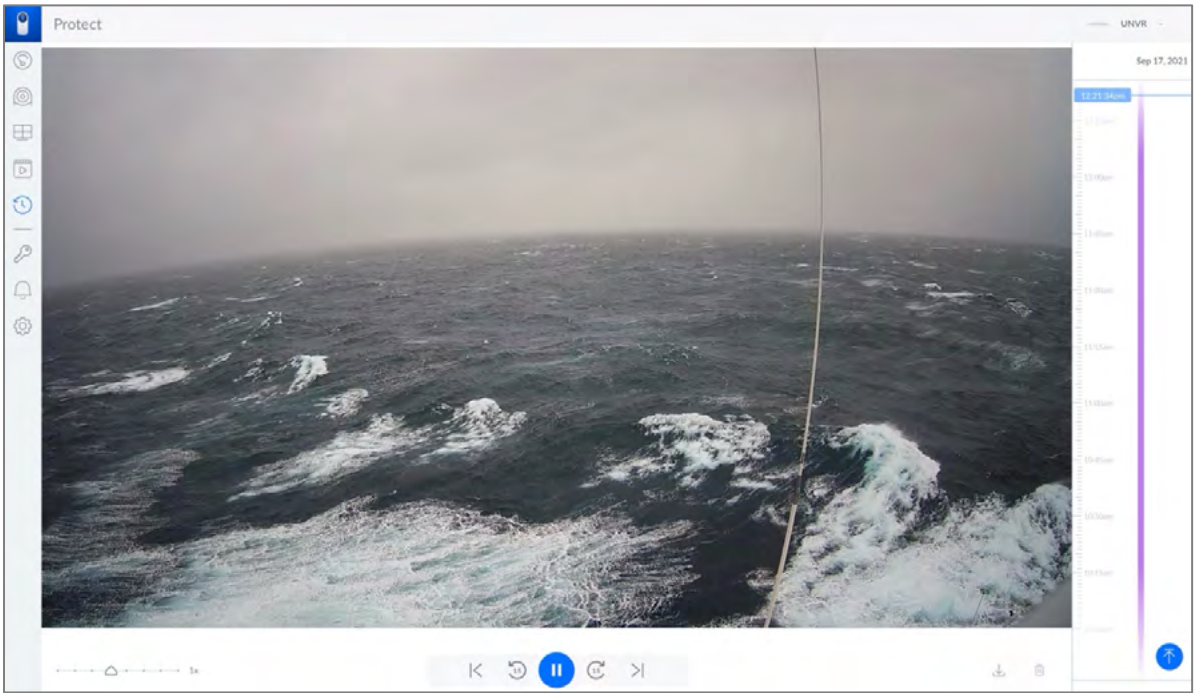

Figure 5. Evidence of Hurricane Larry as an AI 'object' (purple stripe right) on UniFi network video recorder (NVR).

Once our data had been reviewed and tested, we used Cesium Ion (2024), an open-source, three-dimensional, global GIS based geospatial visualisation platform to input our objects in their GPS positions along with icons identifying spatial separation and creator type (Fig. 6). Cesium uses a timeline which allows objects to emerge as they are recorded by our camera's allowing flythrough and time-based investigations via different use cases. A pop-up panel triggered by floating over a sighting allowed basic information on type, location, and a link to our Unifi (2024) cloud-based AI drives that provided short videos of each object. We started considering boundary objects experientially without rich and thick descriptions and found that Cesium was a good candidate in a similar way to how contracts have emerged as central connectors with agency in organisations (Franco-Torresa, Rogers and Ugarellic, 2020). Cesium delivered an ability to handle time, multiple scales from local individual to global, coordinate connections across several software platforms (Cesium Ion 3d geo-spatial platform (2024), Google Sheets, UniFi AI Security (2024), Fleetmon GPS tracking (2024)) and different team members with different disciplines and skills ranging from engineering to computer science, data visualization and co-design. In terms of OOO we see Cesium as a sensual object with capacity to make new connections not only between real objects but across time, space, and diverse actors. It has scope for conceptually aestheticising these relationships providing material for considering both unit operations and carpentry (Bogost, 2012; Linley, Akmal and Colton, 2020). For future work, this may allow data visualisation techniques to facilitate novel object-to-object observations not visible in real-world scenarios, e.g., migration routes, salinity, ocean currents, dissimilar object densities, spatialisation etc.

Figure 6. Cesium Ion GIS trace from Kangerlussuaq in Greenland to Poole in the UK via the Azores, Gibraltar, and Sardinia. Note icons differentiating object types including events (cloud-sun) and spatial separations. RNLI flags (top right) denote a number of applied ocean design projects conducted around the UK influenced by the ocean data (to be reported separately).

We found less direct evidence for the conceptual power of suffixscapes at this stage of the research, but we anticipate the concept of disjunctions could prove powerful when mapped across institutions and geographies to identify imbalances that can be addressed through design action. Actor Network Theory was interesting in the sense that while we were aware of complex networks of actors with the power to leverage significant change and that non-human potential was significant, the resources and complexity of making transoceanic networks with an object-orientated focus is conceptually and technically challenging at this stage. We feel it may be something that has potential in a future evolution of the research or can be prototyped in a more discrete way.

Table 3 shows a summary of our analytical framework comprising of presence, emergence, distance, and value have been used to summarise how we experienced and noted the impact of each of the theories.

Table 3. Post-fieldwork Theory Analysis.

	Presence	**Emergence**	**Distance**	**Value**
Criteria **Theory**	If/where and when we saw evidence of this concept	How this concept came into being into the research	How close, integrated this became in our practices - philosophical to applied	Value gained and type (E.G. theory, data gathering, methods, analysis)
ANT	No clear evidence at this stage of the research, future potential noted.	Considered and retrospectively can be of future value.	No directly applied or considerations changing approach or decisions.	None directly at this stage of the research.
Boundary Objects	Yes, via Cesium Ion as a boundary object media mediator of objects and relations.	Perceiving connections across software stakeholders, objects and hyperobjects.	We became aware of this later into the visualisation and reflection stage of the research.	Useful for understanding role of Cesium beyond data visualisation and how it has centralised ideas.
OOO	Slowly becoming stronger throughout the applied research and directly in reflection stage.	Clear value gained from a new perspective on objects improving their inclusion and actionability in design and beyond human.	This was an active conversation relating to what is/not an object from early stages of the research.	Direct value in identifying new types of objects and considering how they can be additional interests to design and co-design.
Suffixscapes	No obvious direct use, more future potential.	Considered, but yet to play a major role.	Not directly applied at this stage.	None directly at this stage of the research.

As a final speculative deviation, we go back to consider Harman's critique of scientific 'theories of everything' (2018, pp. 25-38) by considering new developments in science. With the recent discovery of ambient quantum superposition (the ability of a particle to be in many places at the same time) in photosynthesis (Lloyd, 2011; Higgins et al, 2021) and Penrose and Hameroff's ground-breaking work on consciousness in Orchestrated Objective Reality (Orch OR) (Hameroff and Penrose, 2014) leading to claims that microtubules in the brain's perceptual boundary are capable of a quantum superposition (Hameroff, 2012), we speculate that from an OOO perspective, an object's ability to 'see' other objects, unit operations and sensuality may not be so far from the leading neuroscience theories of consciousness and physics theories of everything. Now that we know the human brain has quantum superposition potential, we wonder if future visualisation technologies can change the way that waves become particles, losing all information apart from the final reality. This could indicate that we can influence vastly complex and difficult to empathise environments in a new way. OOO from philosophy and string theory (Becker, Becker and Schwartz, 2007) from physics may end up being two sides of the same coin, rather than diametrical opposites. Data visualisation may interfere in the process of Orch OR by creating new objective routes to reduce highly numerous possibilities. Could there be connections between designing experimental spatial data visualisations and the conscious triggering or realisation of quantum biological superposition embodying object-orientated ontology?

6. Conclusions

With the quantitative data gathered and visualised along with some initial stakeholder engagements, we have been able to reflect and speculate on the value of the ANT, OOO, Boundary Objects and Suffixscapes going beyond our initial expectations of providing conceptual stimulation for methods and tools selection. We have found strong affinities between our expanding object definition needs and OOO's real and sensual objects, carpentry, and boundary objects. We have learnt that having several theories circulating in our research has allowed us conceptual breadth, inspiration, and broad scope for genuine emergence of conceptual value to support an emergent methodology. Many smaller decisions were supported or triggered by the theoretical breadth, and this also gave confidence in going beyond traditional design relations between people, objects, events, spaces, and scales.

Our work so far has informed our emergent methodology evolution and promises to provide more support and confidence from theory to reach out into new spaces for engaging broader consideration of who, what and others to include. The significance of this is to find direct value from concepts in OOO including real and sensual objects, unit operations, carpentry and boundary objects that directly influenced our methodology, practices and mental models concerning the research. Furthermore, we have been able to begin grounding several concepts from OOO and boundary objects directly into practice-based design research.

The speculative convergence of OOO in philosophy and quantum physics superpositions in nature is significant. We do not make a claim to connect it here, only to note there are enhanced thoughtful possibilities and converging properties worth exploring through immersive design visualisations. We may come to realise that when we say that we have a strong affinity with the ocean, it may be more than emotional.

KEYWORDS | MULTISPECIES DESIGN, MORE THAN HUMAN DESIGN, SPECULATIVE DESIGN, CLIMATE ACTION, SPECULATIVE ECOLOGIES

ABSTRACT | This paper introduces the concept of “Multispecies Engagement” as a framework to bridge speculative design practices with emerging multispecies and interspecies approaches that challenge the traditional human-centred focus within the design discipline. It emphasizes the necessity of incorporating non-human stakeholders into speculative design processes to address climate-related challenges, such as biodiversity loss, environmental conservation, and energy transitions, among others, thereby fostering social and ecological innovations. This study underscores the critical role of speculative design in tackling these issues and traces its evolution toward multispecies approaches, drawing from interdisciplinary fields like anthropology, amidst emerging socio-ecological challenges, transcending purely technological implications. The discussion is grounded in a mapping of Multispecies tendencies and potentials within design. This mapping identifies fields of action, roles, skills, and responsibilities of speculative designers, prompting further discourse. The goal is to provide guidance on navigating these diverse approaches and delineating the actions required from speculative and future-making designers concerning the potentials and limitations of embracing a multispecies perspective.

1. Climate Change as a Multispecies Design Challenge

Speculative Design Practices (SDP) play a pivotal role in envisioning alternative futures, and making substantial contributions to transdisciplinary and societal transformation processes. Traditionally, their focus has centred on critically examining the social impact and aesthetics of emerging technologies through fictional "What if" narratives and storytelling objects. However, as the climate crisis intensifies, a new frontier emerges, necessitating a shift beyond the technology- and human-centred roots of Speculative Design Practices. To meet this challenge, it becomes imperative to engage non-human stakeholders, such as plants, microbes, insects, and undiscovered and almost extinct species, in shaping solutions for today's complex socio-ecological issues.

This necessity becomes evident when putting human life in perspective: the estimated total number of species on Earth varies widely, with the vast majority believed to be microbial and still undiscovered. When considering only known and described species, humans represent a minimal percentage, estimated at less than 0.01% of the total. Even though this number is a rough estimate, it underscores the importance of envisioning futures that serve purposes beyond human-centric needs. Against this background, this study aims at sharing observations of an ongoing *multispecies turn* within Speculative Design Practices and questions new roles, responsibilities, and research questions that are emerging for the design discipline. Furthermore, this study invites framing climate related and ecological challenges as a *multispecies design challenge*, that requires modes of engagement and knowledge-production with other-than-human beings.

1.1 Interdisciplinary Playgrounds for Speculative Design Practices

The transformative potentials of Speculative Design Practices extend beyond the confines of design discipline. For instance, within the realm of research agendas, such as Responsible Research and Innovation (RRI) (von Schomburg, 2013) methodological approaches of Speculative Design Practices are valued, to include different perspectives from research, policymaking, economy, and society at an early stage of the innovation process, by extrapolating possible developments of emerging technologies with uncertain impacts, such as biotechnologies (Harles & Heidingsfelder, 2021). By embodying these outcomes through fictional narratives, they open debating grounds to discuss societal needs and to include perspectives of everyday life experts. However, against the backdrop of socio-ecological challenges, such as biodiversity loss, new design challenges emerge, that extend beyond technology-centered agenda settings and human needs. But the challenge lies in articulating those needs which interconnections are not always apparent in everyday life.

Furthermore, the potentials of Speculative Design Practices are increasingly recognized within the realm of public sector innovation, policymaking, and democracy. But here as well, the necessity to include non-human agents becomes evident, as the notion of granting legal rights to non-human beings gains traction at governmental levels, exemplified by initiatives like the "Sumac Kawsay" in Ecuador or the "Te Awa Tupua Act" in New Zealand (Kauffmann & Martin, 2018).

Against this backdrop, this study delves into how Speculative Design Practices can effectively respond to the growing demands for inclusivity on societal, political, and environmental levels that go beyond human-centric perspectives.

In the first section, the study emphasizes the impact of interdisciplinary *Multispecies Studies* and *Multispecies Design approaches* that challenge anthropocentric and Western-centric perceptions within the realm of socio-ecological challenges. This is followed by a short overview of the entanglements between design and nature, ranging from "Nature-inspired Design" to an ontological turn.

The main part of this study scrutinizes the evolution of SDP, tracing their roots from *Radical Design*. It showcases significant influences from interdisciplinary touchpoints and maps an emerging multispecies turn. The study culminates in a reflection on the requirements, challenges, and limits of a Multispecies approach in design, illustrated by a prototypical concept of "Multispecies Engagement."

2. A Multispecies Turn: Moving Beyond Human-Centered Ways of Knowing

2.1 Multispecies Ways of Knowing: Theoretical Common Grounds

This paragraph provides a brief overview of the theoretical foundations of *Multispecies Studies* at the intersection of interdisciplinary disciplines of humanities, social sciences and natural sciences. These contributions emphasize the interconnectedness of all living beings, including humans, animals, plants, and microorganisms. By moving beyond anthropocentric and western-centred understandings of nature, Multispecies Studies also challenge new modes of academic knowledge production. Therefore, this emerging field develops new methodologies for studying the agency and perspectives of other-than-human entities, contributing to social and environmental justice. As part of this study's investigation on Multispecies Approaches within the Design discipline, an overview of existing theoretical concepts is crucial. This overview proposes three theoretical pillars, each of them defined by influential concepts and pioneers from different backgrounds:

1. **Sociology & Posthumanism**
   Relevant and influential contributions to understanding multispecies are grounded in sociological and post-humanist concepts—primarily represented by Donna Haraway and Bruno Latour. Haraway's concept of "nature cultures," "companion species," or the "Chthulucene" challenges the traditional divide between nature and culture, emphasizing the complex and mutual entanglements between humans, animals, and the environment. Latour's actor-network theory highlights the agency of non-human actors in social networks (Latour, 2007), and his concept of "parliaments of things" proposes a new way of thinking about the relationship between humans and non-humans by emphasizing the need to understand the complex networks of actors and their interactions (Latour, 1993).

2. **Anthropology and Environmental Histories**
   Building on the foundations laid by Haraway and Latour, key concepts have emerged at the intersection of anthropological sciences and environmental history, specifically that of *Multispecies Ethnography* (Kirksey & Helmreich, 2010*), Multispecies* Assemblages (Aisher & Damodaran, 2016)*, Multispecies* histories (Loewenhaupt-Tsing et al., 2019) describing an *ontological and non-human turn (Grusin, 2015)*. These approaches have, in common, that they recognize the interconnectedness and inseparability of humans and other life forms from an anthropological perspective. They are emphasizing the agency of other-than-human species, highlighting the environmental, political and economic dimensions of human-nonhuman relations. The intersection of anthropological and environmental research, a contributing with valuable interdisciplinary methodologies for studying complex human-nonhuman relations.

3. **A Symbiotic View Of Life from a Natural Sciences Perspective**
   Recent findings in natural sciences challenge the perception of life forms as individual, independent entities. Gilbert's work on "A Symbiotic View of Life: We Have Never Been Individuals" advocates for re-evaluating the concept of the "biological individual" (Gilbert et al., 2012). Furthermore, the introduction of the "holobiont" discussed in natural science recognizes the multispecies assemblages comprising the multicellular eukaryote and its

persistent symbionts. This shift, influenced by Lynn Margulis, emphasizes the significance of symbiosis and cooperation in biological systems. Horizontal gene transfer further elucidates symbiotic evolutionary developments. These scientific foundations underpin multispecies ethnography, exploring the interconnectedness of human societies with the non-human world. Incorporating developments in environmental, conservation, and evolutionary biology into multispecies approaches enables interdisciplinary exploration of relationships between humans, non-human beings, and their microbial symbionts. This approach sheds light on how these relationships shape culture, society, and health.

These developments are paving the way towards new ways of knowledge production in academia that can lead to a fundamental culture change in Western-centric research institutions.

3. Human and Non-Human Entanglements Through Design

The entanglements of the human and non-human worlds within design practices are vast, forming a significant part of design history that is shaped by scientific and technological developments. To comprehend the mutual benefits between Multispecies Studies and the design discipline, this paragraph explores the roots of interconnected relationships between humans and their natural world within the design process, by proposing three concepts:

1. **Nature-Inspired Design: Nature as a Source of Inspiration**
   Nature has influenced various design domains, including product design, material design, architecture, and technology. Learning from nature, by adopting principles or mimicking movements, material qualities, and functionalities, has resulted in nature-inspired prototypes and concepts such as Biomimicry Design or Biodesign (Sachs, 2016). By engaging with nature as source of knowledge, other-than-human beings inform the design process. Here, designers are drawing inspiration from nature and seek nature-based knowledge, rather than opposing it. However, caution is essential to ensure that the design outputs benefit both human and non-human entities, considering ecological sustainability and ethical production.

2. **Transition Design, Eco-Social Design & Pluriversal Design: Designing for Eco-Social Transitions**
   Further developments that can be observed within the design discipline are approaches that consider the entanglements of social, political and ecological impacts of design. Its roots can be traced back to influential concepts evolving in the 1970s, such as Viktor Papanek's "Design for the World," or Buckminster Fuller's works on the "Operating Manual for Spaceship Earth." They are emphasizing the need for functional, sustainable, and accessible designs that address the needs of all people, marginalized groups, and the environment. In contrast to nature-inspired design, the role extends beyond generating tangible design outputs. It is elevated to a systemic level that connects societal, political, and ecological perspectives.
   The systemic role of design is negotiated against the backdrop of current socio-ecological challenges and is expanded through approaches such as Transition Design (Irwin, 2015), Eco-Social Design (Krois, 2020) or Pluriversal Design (Escobar, 2017). These approaches distinguish themselves by not aiming to develop final solutions, but by using design to raise ecological, political and socially relevant questions. They are democratizing the design process, enabling co-creative, participative, interdisciplinary design processes that involve pluriversal perspectives from communities, society, politics, science, and economy. This requires common grounds for societal debates and desirable visions of the

convivial futures. The importance of Speculative Design approaches, which often open space for alternative realities and imaginaries of the future, is particularly evident here, as illustrated in the next paragraph.

3. **More-than-Human Design**
   In response to escalating environmental concerns and ethical considerations of novel technologies, such as Artificial Intelligence, the design discipline undergoes a paradigm shift from a human-centred to more-than-human approaches (Gatto & McCardle, 2019; Hook, 2019; Mancini & Lehtonen, 2018; Metcalfe, 2015). Multispecies and interspecies approaches, often inspired by the three theoretical pillars outlined above, advocate for the active involvement of other-than-human agents as clients of design. These methodologies can be observed at the intersection of urban planning, material design, and human-machine interaction.
   More-than-human Design is not only narrowed to other living species, such as animals or bacteria. Its scope encompasses every entity on this planet, from the technosphere, biosphere or geosphere. These considerations lay the groundwork for exploring the potentials of Multispecies Studies and Speculative Design, establishing a necessary framing for further inquiry.

A retrospective of the entanglements between nature and design within the past decades is relevant to explore the evolution of a Multispecies Turn in Speculative Design Practices outlined in the next paragraph.

4. A Multispecies Turn in Speculative design?

4.1 From Radical Design to Speculative Ecologies

In this exploration, Speculative Design Practices encompass a collective category of design approaches whose origins trace back to the 1960s with movements like *Radical Design* and *Critical Design*. Over the past two decades, a diverse array of SDP methodologies has emerged, including Speculative Design (Dunne & Raby, 2013), Design Fiction (Bleecker, 2009; Bleecker et al., 2022), Adversarial Design (DiSalvo, 2012), Associative Design (Malpass, 2013), Discursive Design (Tharp & Tharp, 2018), Critical Artifact Methodology (Bowen, 2009), and Speculative Enactments (Elsden et al., 2017).

These approaches share a common objective: to detach design from market-oriented utility and the creation of ready-made consumer goods. Instead, they use design to interrogate societal, technological, economic, and ecological developments and their interconnections. Rather than simply describing how things are, these practices generate fictional narratives and storytelling prototypes of alternative futures and sooner-nows to stimulate societal discourse. The designed outputs are considered as research artefacts (Matthews, 2014), “diegetic prototypes” (Kirby, 2010), "provotypes" (Boer & Donovan, 2012), or “boundary objects” (Heidingsfelder et al., 2019) embodying the intricate interweaving of societal and technological developments. Unlike design prototypes for consumer goods, these artefacts do not describe functionality; instead, they aim to pose questions and foster collaborative inquiries on how things could be. In this way, these artefacts break down the complexity of future impacts, translating technological and scientific feasibilities into everyday scenarios, while creating a space for collaborative exploration of how we want to co-exist with new-to-everyday life artefacts.

Speculative Design Practices are increasingly recognized beyond the confines of the discipline, particularly for engaging the public in scientific and technological innovations. This recognition allows for early-stage assessments of acceptance of novel technologies in both the public and private sectors. However, there is a risk of a technocratic misunderstanding of these approaches, which consider potential developments through a solely human-centric lens, seeking to address complex challenges primarily through readily

applicable technological solutions, while overlooking broader societal and political implications. This limited perspective, often rooted in Western, and capitalist world views, frequently disregards environmental consequences and fails to acknowledge the wealth of cultural knowledge and diverse perceptions of the world (Tunstall, 2013). Therefore, it is crucial to consider the ethical responsibilities of SDP in the context of socio-ecological challenges before expanding these approaches towards Multispecies Studies (Harles & Heidingsfelder, 2021). There is a need for an ontological turn, that considers societal developments that call for decolonized, pluriversal and inclusive futures that expand the realm of SDP through new approaches, such as Afro-Futurism or Indigenous Futurism (Harrington et al., 2022).
Against this background, the reconsideration of Multispecies Studies within SDP means to integrate a multiplicity of perspectives and speculative ecologies (Armstrong, 2021), that are considering the complex relationships between humans, cultures, non-humans, and the environment.

4.2 Evolutionary Roots of Speculative Design Practices

The following paragraph provides a brief overview of the development of Speculative Design Practices (SDP) over the past 30 years, highlighting its inherently close connections to human history and technological advancements.

The roots of SDP can be traced back to Radical Design, a design movement that emerged primarily in Italy during the 1960s and 1970s. It arose in response to the social, cultural, and political upheavals of the time, forming part of a broader countercultural movement that aimed to challenge established norms and question the role of design in society. Radical Design sought to break away from traditional design conventions, exploring new ideas, materials, and forms.
In the 1990s, Dunne and Raby developed the concept of speculative design to challenge the conventional view of design as a problem-solving activity. They aimed to explore the potential of design as a tool for thinking and speculation about the future, influenced by societal, political and technological developments. This marked a shift from strategic future thinking prevalent during the Cold War, characterized by scenario planning and predictive approaches. In contrast to this strategic understanding, Speculative Design argued for viewing future scenarios not as final goals but as mediums to enable collaborative debates and “social dreaming” of many possible futures.

Simultaneously, the affordability and widespread use of electronic devices, especially computers, began to impact various aspects of our lives. This raised questions about the usability, aesthetics, and future roles of electronic products in society, laying the conceptual foundations for what Dunne and Raby defined as Critical Design. Critical Design proposes the use of design as a tool for questioning and critiquing the role of products and technology in society, encouraging debate and speculation about possible futures. Since the 2000s, SDP has witnessed a rich biodiversity of approaches building upon these conceptual foundations, that go beyond the scope of this paper. However, three fundamental concepts, that lead to relevant evolutionary developments within SDP, will be highlighted in the following.

4.3 The Mundane Turn: Sooner-Nows and Speculative Enactments:

Despite being rooted in future-making methodologies, Speculative Design outputs do not exist in a “futurist vacuum.” The conceptual roots of SDP connect present challenges and developments with potential future outcomes. To ensure public engagement within speculative practices, future scenarios must be understandable to a broad audience. There has been a call from a design anthropological perspective to align Critical and Speculative Design Practices with everyday life situations, creating “mundane” futures rather than opening fictional narratives beyond our expected lifetime (Auger, 2013; Kjærsgaard & Boer, 2015).

By linking speculative scenarios to everyday realities that describe the impact and frictions of emergent technologies in mundane situations, it establishes a direct connection to the audience. Given the societal relevance, there has been a questioning of access to SDP outputs, often presented as passive objects in museum contexts. The focus is not only on situating these scenarios in everyday application contexts but also on the experiential aspect through immersive scenarios or so-called Speculative Enactments (Elsden et al., 2017). Additionally, the role of SDP artefacts has been scrutinized, with designers not only crafting artefacts but also involving the audience and non-designers in the process. This participatory approach allows different personal perspectives to be considered, enabling societal groups to articulate needs and desires for future scenarios (Heidingsfelder et al., 2019).

This shift, termed by the author of this paper as the “Mundane Turn” in Speculative Design Practices, aims to argue for a more profound and responsible understanding of SDP, particularly in addressing urgent environmental challenges that demand immediate action and prevent problems from being deferred into an intangible future.

4.4 The Biotechnological Turn

In addition to a paradigm shift in temporal aspects within SDP, there is also a thematically driven transformation to consider, which will be explained in the following paragraph.

Significant technological developments that have rapidly gained momentum in the past 20 years, turning our understanding of nature upside down and challenging the boundaries between human-made and nature-made, are the field of Modern Biotechnology and Synthetic Biology. Through them, humans have not only learned to decipher the code of life but also to rewrite or redesign it entirely, and at increasingly affordable costs and time investment. This technology brings forth fundamental ethical questions and tremendously complex impacts on society, the economy, politics, and the environment. Its significance is underscored as it is declared as a key technology at political levels within a short period, prompting inquiries into global ethical standards.

This technological development does not go unnoticed in SDP and forms the basis for an expanded line of questioning that not only incorporates humans and technology but actively includes nature as a stakeholder in the speculation, thus re-examining the boundaries of SDP (Dunne & Raby, 2013). The engagement with biotechnological implications on society through interventionist speculative design methods is referred by the author of this paper to as the "Biological Turn." This turn is exemplified by numerous contributions, as illustrated in the following through exemplary use cases.

- Emilia Tikka's work "ÆON" envisions a future where the biological clock can be reversed by genetic reprogramming. The project is embodied as a device for daily use and narrated as a fictional story of a couple who made opposite choices about using the rejuvenating technology 60 years ago and now must face the consequences of their decision. The project aims to question the human desires and dreams driving current biotechnological innovations, and societal dimensions of the idea of prolonged lifespan, raising philosophical questions about human life, death, and the afterlife.

- The Pink Chicken Project by the Nonhuman-Nonsense Collective proposes using a “Gene Drive” to change the colour of the entire species of chickens to pink. This is in response to the impact of human-made materials on marine life, with the bones of 60 billion chickens killed every year leaving a distinct trace in the rock strata. The project aims to change the future fossil record by modifying the genetic makeup of chickens, turning them pink, and using the recently invented Gene Drive technique to spread this gene on a global scale. Raising questions about the impact and power of synthetic biology and gene drives, and invites the public to reflect about the incentives and impacts. However, it highlights the need for an ecological discourse that includes

issues of social justice and the radical restructuring of society needed to break the death grip of the sixth extinction.

- An interdisciplinary example of Speculative Design at the intersection of biotechnology is the work of Dr. Pinar Yoldas, who combines design, synthetic biology, and cultural criticism to coin *Speculative Biology*. This field involves the design of tissues, organs, organisms, biological systems, ecotypes, and ecosystems to catalyse creative critical thinking about the ethical and cultural implications of biotechnology. In her project "Ecosystem of Excess" features a series of speculative organisms that live in an ocean of plastic waste, highlighting the impact of human-made materials on marine life. The project uses synthetic biology to design organisms that can survive in this extreme environment, such as a jellyfish that feeds on plastic particles and a shark that has evolved to swim through plastic waste.

- Another prominent example is the work of Daisy Ginsberg, who uses design to explore the potential implications of synthetic biology. Her project “Synthetic Kingdom” imagines a world where synthetic organisms have been designed to perform various functions, such as cleaning up oil spills or generating energy. The project emphasizes the need to consider the ethical and societal implications of creating new life forms. Furthermore, her project "Designing for the Sixth Extinction," which explores the use of synthetic biology to save endangered species. The project uses SDP to spark a dialogue between the conservation and synthetic biology communities about the ethical implications of using biotechnology to save existing, “natural” organisms.

Figure 1. ÆON by Emilia Tikka| Photograph by Zuzanna Kaluzna.

Figure 2. Pink Chicken Project by Nonhuman-Nonsense.

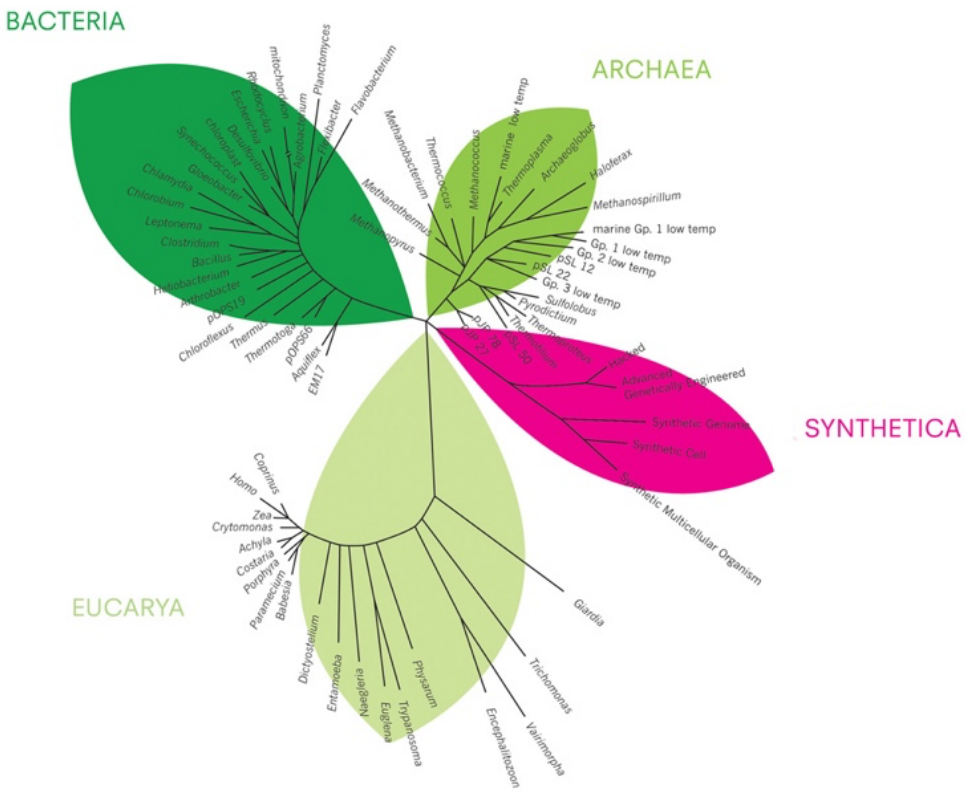

Figure 3. Synthetic Kingdom by Alexandra Daisy Ginsberg.

These use-cases exemplify the application of Speculative Design Practices to explore the boundaries between nature, humanity, and technology, concurrently prompting critical inquiries into the ethical and cultural implications of such advancements. The advent of the Biological Turn significantly contributes to the evolution and potential of SDP, particularly in addressing socio-ecological challenges. This shift places non-human protagonists and speculative living artifacts at the centre of Speculative Design Approaches.

Despite the intended focus of these projects on highlighting current environmental issues and posing essential questions, it is imperative to note that the primary emphasis lies on technological feasibilities and human impacts, rather than intercultural and non-human implications. The biotechnological outcomes, such as genetic modifications to non-human entities or extending human lifespan, are predominantly contemplated from a human-centred perspective, lacking consideration for the perspectives of surrounding ecosystems and non-western cultures.

In summary, the Biological Turn illustrates how SDP can facilitate holistic storytelling for collaborative inquiry into environmental issues, positioning non-human entities as central protagonists. However, there exists a potential risk of perceiving these non-human agents merely as artificially implemented living technological interfaces in natural habitats, serving human-centric benefits. Consequently, there is a pressing need for a more radical inclusion, which will be expounded upon in the subsequent paragraph.

4.5 The Multispecies Turn

Expanding on the reflections discussed above, it becomes apparent that there is a compelling necessity for the continued evolution of Speculative Design Practices in addressing intricate socio-ecological challenges, such as biodiversity loss, rising temperatures, and sea levels. A spectrum of experimental use-cases and practice-based design research projects has already emerged, positioning themselves at the intersection of these challenges and multispecies studies. These projects can be recognized as pioneers, navigating the boundaries and challenges inherent in adopting multispecies approaches within speculative design practice.

These initiatives traverse various fields of action intimately connected with everyday life, encompassing environmental conservation and multispecies in urban habitats (Roudavski, 2021; Sheikh et al., 2023), prototypes for enhancing coastal regions (Metcalfe, 2015), explorations of human-plant interactions (Gatto, 2019), and efforts focused on fostering empathy for non-human entities through Animal-Computer Interaction (Hook, 2019). Employing speculative and immersive methodologies, these projects ponder how socio-ecological challenges can be envisioned from a more-than-human perspective.
Moreover, these endeavours are generating pertinent research questions that explore methodological frontiers and interdisciplinary playgrounds at the crossroads of multispecies ethnographies, conservation strategies, and biological impact assessments. Going beyond mere speculation, they actively seek collaborations with scientific experts, non-governmental organisations, local communities, and stakeholders. By building bridges and facilitating knowledge transfer, they strive to cultivate meaningful collaborations extending beyond public debates, translating into tangible actions for socio-ecological betterment. In doing so, they contribute to a more nuanced and actionable approach in the evolving landscape of speculative design, integrating theory and practice to address urgent socio-ecological challenges.

5.A Multispecies Engagement Framework

5.1 Engaging Other-Than-Human Agents Through Speculative Design

In light of the preceding discussion, this study introduces the concept of a "Multispecies Engagement Framework," proposing a paradigm shift in speculative design interactions with non-human entities in socio-ecological transitions that aim to take climate action. In this study, the term is inspired by *Public Engagement with Science (PE)* (Schäfer, 2019*)* which delineates a participatory approach to science communication fostering a mutual dialogue between science and society. Public Engagement and participatory practices are evolving as strategic pillars within research institutions, aiming to involve the public in their research agendas to create impactful outcomes aligned with societal needs.

Speculative Design Practices have demonstrated their potential to involve societal stakeholders in Public Engagement formats through design-based methodologies, using speculative future scenarios as a collaborative platform of exchange and inquiry (Heidingsfelder et al., 2019).

In the context of pressing ecological challenges, this study posits the hypothesis that SDP, aiming to engage communities within ecological transitions, needs to take the ontological turn into account. It renegotiates the influential concept of PE, primarily focusing on incorporating human needs into scientific research. There is a risk that PE keeps perpetuating a human-centred (and Western) bias into research agendas, excluding cultural perspectives and ecological impacts, particularly concerning overarching societal issues at the intersection of sustainability and conservation. As communities and environments are impacted by ecological challenges in very different ways, there is a need to expand the modes of engagements. Against this backdrop, the concept of Multispecies Engagement expands the notion of “the public” beyond the human scope. So, what and who constitutes a “Multispecies Public”?

The proposed concept “Multispecies Engagement” advocates for establishing a mode of engagement that includes other-than-human beings within research and innovation processes, aiming to create transformative change within the scope of socio-ecological challenges. This concept serves as a bridge between design, society, nature, science, and pluriversal perspectives and drives ecological, environmental and multispecies justice through a *multispecies way of knowing*.

5.2 Methodological Approach and Use-Cases

The multispecies framework builds upon the developments in Speculative Design Practices (SDP) discussed earlier, focusing on collaborative inquiries for socio-ecological imaginaries of the future by translating complexity into everyday scenarios, and engaging diverse cultures, modes of knowledge, and interdisciplinary expertise.

This framework is constructed through a methodological mapping of practice-based design literature centred around multispecies, interspecies, and more-than-human design interventions, aiming to address socio-ecological challenges in collaboration with or for other-than-human entities. Given that this field is still in its nascent stages, the framework also incorporates use-cases that may not explicitly align with Speculative Design Practices. However, they share the same values and aspirations. Their ambition to engage other-than-human beings within their design process and exploration of interspecies methodological approaches makes them a relevant source of knowledge. Some investigated use-cases are highlighted below to provide an overview of what can be defined as multispecies design practice.

- Daniel Metcalfe's dissertation “Multispecies Design” (2015) introduces a design approach recognizing animals as clients of design, human-animal interactions as designed experiences, and man-made systems as extensions of ecological systems. The research addresses designing for biodiversity in human-dominated habitats, emphasizing the physical and socio-cultural requirements. The developed *Principles and Tools for Multispecies Design* aim to shift practices towards more sustainable and biodiverse human habitats.

- Alan Hook's paper on "Exploring Speculative Methods" (2019) proposes using speculative design to understand nonhuman animals and foster interspecies understanding. The Equine Eyes prototypes explore human-horse interactions, challenging anthropomorphizing nonhuman animals. The paper argues for creating experiential artifacts in speculative design and highlights the role of design in suggesting arguments about the world.

- The paper "Reparative futures of smart urban governance: A speculative design approach for multispecies justice" by Hira Sheikh, Peta Mitchell, and Marcus Foth (2021) explores the potential of speculative design to create more just urban environments for both humans and non-human species. The authors suggest a framework considering the needs and perspectives of all urban inhabitants, using speculative design to investigate the potential of urban governance for environmental justice and species equality.

The methodological mapping analyses these and other projects, identifying approaches, similarities, and blind spots to refine the understanding of how multispecies frameworks and speculative design can be effectively employed.

5.3 Aspects of a Multispecies Engagement Framework

The following paragraph highlights seven main principles that build the conceptual foundation of the Multispecies Engagement Framework to engage other-than-human stakeholders within SDP.

1. **Anticipating Otherness**
   Speculative design critically examines anthropocentrism, challenging the prevailing human-centric worldview. It seeks a more profound understanding of the non-human sensorium, encompassing the sensory experiences and perceptions of non-human beings. This raises the question of who has not yet been considered, requiring an initial comprehensive understanding of protagonists, dependencies, and frictions in

ecosystems. To achieve this, we must first overcome our human empathy biases towards significantly different mammals and dissolve classifications between domesticated, wild, and utilitarian animals.
Furthermore, other-than-human beings include not only animals and other species that are visible to human eyes, with which we already have a connection. It is crucial to consider microorganisms, bacteria, fungi, and ecological agents, such as soil, air, and water as well that present different modes of otherness than that of mammals, birds, or fish. Above all, it is essential to understand that all beings are part of an ecosystem, indirectly affected regardless of their dependency relationships. So multispecies world building is a complex entanglement of different modes of otherness, that needs to be anticipated.

2. **Levels of Engagement: From Co-Producers to Clients of Design**
Speculative design approaches, depending on their goals and processes, offer various possibilities for involving non-designers. This results in different roles, such as that of the informant or consultant, providing expertise to the designer. Participants, representing the affected target groups, are engaged through speculative artifacts, ranging from informants shedding light on challenges from their perspective to co-designers actively involved in shaping artifacts. These levels of engagement must also be questioned in multispecies approaches. In addition to considering whom the designer includes, there is the question of how other-than-humans can be involved—ranging from co-production, such as material development, to "clients of design" like the intertidal species in Daniel Metcalfe's project, to "informants" highlighting challenges from their perspective.

3. **Fields of Action and Interdisciplinary Playgrounds**
The application realms of Multispecies Engagement within Speculative Design Practice are as varied as the challenges it addresses. Key themes revolve around participatory processes in urban habitats, converging design, architecture, urban planning, and environmental sciences. These initiatives explore how urban spaces can be designed for both humans and non-humans, recognizing cities as crucial habitats and "urban arks" for various species. This perspective shifts urban structures from "Anthropocene objects" to new to nature ecosystems, optimizing them as protected habitats through strategies like Rewilding, Assisted Migration, or Grey Greening.
These applications extend beyond urban spaces to rural areas. For instance, Metcalfe's exploration of optimizing a Coastal Pipeline as a shared habitat involves approaches from Multispecies Ethnography (Kirksey & Helmreich, 2010), Reconciliation Ecology (Rosenzweig, 2003), Cross-Species Engagement (Hinchliffe et al., 2005), and embodied design interventions (e.g., prototypes of tiles).
Rasa Weber takes it further by introducing concepts of Interspecies Architecture in critical maritime zones like coral reefs, coining the term *Sympoïetic Design* (Weber, 2022). Inspired by Lynn Margulis's theories, this approach combines materials research with behavioural biology and Living Architecture to create artificial reefs tailored for non-human marine environments.
Approaches at the intersection of material research and food production, such as Emma Sicher's work, bridge design, anthropology, and molecular biology. Sicher explores human-plant-microbe interactions, envisioning "Multispecies Matter" as an adaptable open design model promoting regenerative practices and resilience in diverse contexts (Sicher et al., 2023).
Projects like the *Interspecies Designstudio*, led by Jannis Kempken, engage non-human as co-designers to produce colours or decay materials. Other mentionable speculative

endeavours at the intersection of Environmental and Multispecies Justice consider other-than-human beings as eligible actors in democratic processes (Sheikh et al., 2023). Furthermore, projects situated at the intersection in Animal Aided Design and Animal Computer Interaction aim to make species' sensorium accessible to humans, promoting empathy through design (Hook, 2019).
Their focus is on opening negotiation spaces and perspectives through interdisciplinary, research-based practice, rather than developing final market-ready products. Despite lacking a specific timeframe, these projects address various environments, from cities to underwater realms and research laboratories.

4. **Engaging Multiplicity Modes of Knowledge-Production**
Engaging communities within speculative design processes requires empathy with communities and an understanding about everyday life realities. Expanding these requirements to a non-human perspective, traditional human-centred design approaches, such as interviews and cultural probes, reach their limits.
Here it becomes crucial to engage with scientists, communities, and local knowledge holders, that have a certain knowledge about other-than-human beings through research, observation or co-existence, while incorporating their perspectives into the design process. Therefore, Multispecies Engagement in SDP necessitates interdisciplinary knowledge development, including scientific, local, or indigenous knowledge. It is important to be aware and embrace various forms of knowledge production beyond academia. Overcoming interspecies barriers may also engage spokespersons for certain species, primarily with scientists, local communities, environmentalists (Metcalfe, 2015). Another crucial step is that designers need to immerse themselves in the environment, spending time observing or embodying movements through somatic practices or technological enhancements to adopt non-human perspectives. This approach entails assessing specific knowledge about how other-than-humans might be affected by socio-ecological challenges. Additionally, designers need skills to navigate through environments that may not be natural habitats for humans (ocean), spanning activities from diving and snorkelling to working in biolabs. Multispecies Engagement challenges designers to step out of their comfort zones within design studios.

5. **Mundane Futures and Non-Human Time Scales**
This principle involves considering time, a central aspect in Speculative Design Practices. Whether exploring alternative presents, mundane futures, or distant scenarios, time frames the speculative design process, providing perspective and orientation for reflection.
Understanding the timescales in which other-than-human entities can adapt to ecological challenges, such as forest dieback or migrating insect species, is crucial. Non-human beings operate on different timescales than humans, influencing their interactions with the designed environment. This understanding, incorporating short lifespans of flies (a few days) or the long lifespan of trees (up to more than 1000 years), should inform the design process. Respecting non-human time scales is essential in creating sustainable, resilient, and just designs with long-term impacts on diverse species and ecosystems.
This principle signifies a shift from anthropocentric to eco-centric design practices, prioritizing the diverse needs and perspectives of non-human beings. By integrating an understanding of non-human time scales into the design process, designers can foster coexistence, collaboration, and mutual flourishing between humans and non-humans.

6. **Non-Human Sensory Toolkit**
   This principle highlights the necessity to think outside our human sensory realms and language-based communication. Humans are not able to grasp the manifold ways in which natures communicates, such as sounds, colours or molecular messages that cannot be perceived by our bodies and nervous systems. This multisensory biodiversity opens new question for practice-based research on how designers can include non-human communication channels within SDP.
   Furthermore, we need to anticipate this kind of otherness, without anthropomorphizing or romanticizing other-than-human beings, as this can risk to misleading the debate.

7. **Measuring Impact and Transfer**
   To ensure the practical application and sustained impact of speculative design beyond debates, a transfer within and outside the design discipline is necessary. Alternative methods of impact measurement, such as ecological indicators, should be employed to assess the effects of design interventions on non-human beings and ecosystems, highlighting the socio-cultural, ecological, and ethical dimensions of speculative design.

6. Conclusion

Over the past decades, Speculative Design Practices responded to social and technological developments with transformative potentials and challenges. Against the backdrop of pressing ecological issues, SDP are confronted with new challenges and developments, such as the multispecies turn. This calls for a shift from human-centred to multispecies ways of knowing, that engages other-than-human beings in the co-creative and discursive approaches of SDP. Thus, it will become crucial to push the disciplinary boundaries of the design field once more and draw together a multiplicity of knowledge, that extends beyond human, western and scientific understandings of nature.

Despite the promising potentials that SDP has to offer to create new ways of multispecies ways of knowing, it is important to critically reflect boundaries and expectations of interspecies collaborations, as every multispecies intervention is ultimately initiated by humans. This initiation always follows the motivation that our efforts serve the purpose of ensuring our survival. Humans are likely the only species aware that they will die and that are aware that they are currently depriving the basis for life themselves. Human bias cannot be avoided, but this is not a reason to not pursue further investigations into the possibilities of Multispecies approaches through design.

The real potential lies not in fostering interspecies collaborations but, above all, in breaking through thought patterns of thought that have shaped our society and academic research for centuries. It is a shift away from unlimited technological progress, especially a shift in the Western-centric and repressive understanding of nature, influenced by Western concepts and views through the spread of natural history museums.

Multispecies Engagement is a path to multispecies ways of knowing or “tentacular thinking” as Donna Haraway aptly puts it, breaking with the human-centred tradition of design. It frees design from the shackles of one-dimensional perspectives and the economic benefits that have tried to domesticate it through terms like Design Thinking. To summarize, Multispecies Engagement is an invitation to raise awareness, switch perspectives and to building bridges between design, politics, science, and society and non-human realities. What is known is worth protecting.

KEYWORDS | SPECULATIVE DESIGN, DESIGN EDUCATION, FUTURE IMAGINARIES, TECHNOLOGICAL DREAMS

ABSTRACT | This paper examines how an emerging technology can transition from the habitat of the laboratory to everyday life, with a particular focus on the different roles design can play throughout this process. Design is intrinsically linked to notions of the future, through the arrangement of elements to accomplish predetermined goals. More familiar is design's near-future role – the arrangement of existing elements to create useful, marketable objects. However, design also has an important role in longer-term planning through the arranging of potential elements to create hypothetical objects and related future imaginaries – visions of how the future could be, should that technology reach maturity. First, we trace the typical journey of a technology through three distinct phases: from its 'genesis' in a scientific laboratory, through the 'imaginary' phase where the emerging technology's potential is transformed into a vision of how the future could be, to the development of an actual product or service for use in everyday life. Next, we present a list of reasons why dreams of the future have stagnated, with an emphasis on how design is implicated in this process. Finally, we present three speculative design projects by PhD students, each working in a different phase of the tripartite process: placing the designer in the laboratory to upstream prototype and infuse scientific research with social responsibility and/or domestic sensibilities; revisiting stagnant technological dreams and updating through the counterfactual history approach; and downstream 'super testing' using speculative methods to better understand the implications of technologies in everyday life.

1. Introduction

The practice of design is intrinsically linked to notions of the future, both near (months and years) and relatively near (years to tens of years), through the arrangement of elements to accomplish predetermined goals (Eames, 1972). More familiar is design's near-term role – arranging existing elements to create useful and desirable objects that can be sold on the market. However, design also has an important role to play in longer-term planning through the arranging of *potential* elements (for example, emerging technologies) to create hypothetical objects and related dreams and visions of how the future *could* be should that technology reach maturity.

In the second section of this paper, starting from a diagram, we trace the typical journey of a technology through three distinct phases: from 1) its 'genesis' in a scientific laboratory, through 2) the 'dream' phase where the emerging technology's potential is transformed into visions of possible futures (both utopian and dystopian), to 3) the development of an actual product or service for use in everyday life. During the 20th century, the middle 'dream' phase became increasingly important in shaping the technological future. Such dreams take on a variety of forms, exist for a plurality of reasons, and inform futures in complex ways. We will focus predominantly on socio-technical imaginaries (STIs) described by Jasanoff & Kim (2009) as 'collectively held, institutionally stabilised, and publicly performed visions of desirable futures, animated by shared understandings of forms of social life and social order attainable through, and supportive of, advances in science and technology'. STIs are particularly helpful because they encode not only the visions of what developments in science and technology might bring but also an entrenched notion of a society's shared value system – the invisible forces that inform and define pathways into the future.

To illustrate the journey of a technology, we will present two case studies that represent the dominant 20th-century Western (US) imaginary, with a focus on the role of design. The belief systems at the core of this imaginary continue to influence contemporary visions of the future and what is seen as the 'good life' despite the mounting evidence against its ideals and methods. The third section offers a list of five reasons why future visions have stagnated or are simply inappropriate for the 'polycrisis'-ridden world of today.

We are in desperate need of new imaginaries. In the short term, we must develop better ways of challenging and exposing the limitations of the existing model. As a starting point towards more appropriate approaches, in the fourth section we present three ongoing speculative design projects by PhD students. Each project acts in a different phase of the tripartite process described above, and presents new design methods and approaches that address the limitations and flaws of the dominant socio-technical imaginary and design's role in shaping it.

2. The Journey of Technology

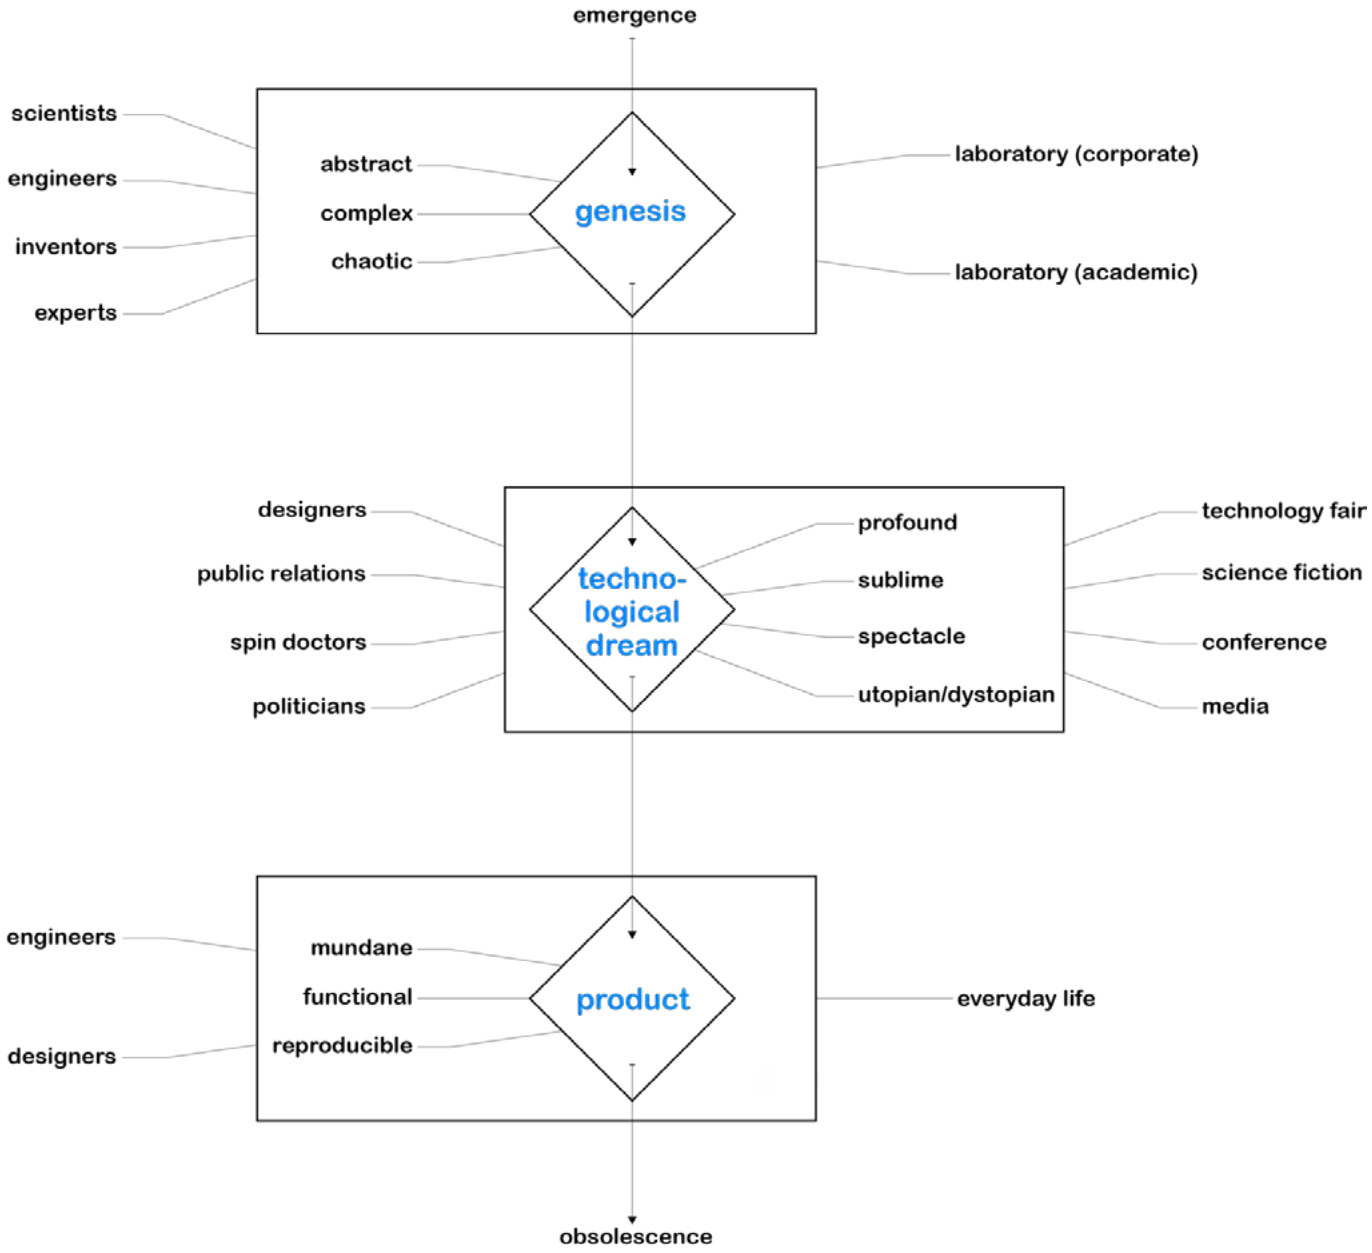

Figure 1. The journey of a technology: The diagram describes the (fairly typical) journey a technology makes from its genesis as an emerging technology in a laboratory, through the technological dream phase before transitioning into real products that exist in the context of everyday life. Finally, the technology descends into obsolescence as it is replaced by more advanced iterations. On the left are the actors involved at each stage and on the right are the contexts.

The diagram in Figure 1 describes, in general terms, the typical journey a technology makes, starting from its genesis in the laboratory through to its ultimate obsolescence. At its genesis the technology is abstract and complex, its behaviour and potential are only properly understood by the scientists responsible for its development.

Next is the technological dream phase. Here the *potential* of the emerging technology is translated into (typically) techno-utopian visions of the future. According to Basalla (1988):

> "Technological dreams are the machines, proposals, and visions generated by the technical community, whether in the Renaissance or the present time. They epitomise the technologists' propensity to go beyond what is technically feasible. Fanciful creations of this kind provide an entry into the richness of the imagination and into the sources of the novelty that is at the heart of Western technology."

Technological dreams take on a variety of forms, exist for a plurality of reasons, and inform futures in complex ways. In this paper we focus predominantly on socio-technical imaginaries (Jasanoff & Kim, 2009). During the last century this *imaginary* phase became increasingly important in cementing the fundamental belief in technological progress and the consequent shaping of the technological future.

The last phase of the journey is the translation of aspects of the dream into the products of everyday life. The iterative nature of technological evolution (Heilbroner, 1967) typically results in the new technology simply being applied to existing product lines. This has become the industry standard model of product development and facilitates generational iterative advances, typified by items such as the iPhone. As the (once) emerging tech reaches everyday life, it is usually quite conservative and familiar – just enough of an advance to make the new product slightly more desirable than its predecessor. Finally, the product descends into obsolescence as it is replaced by more advanced iterations. In certain cases, the dream gets recycled or regurgitated; for example, the recurring dreams of domestic robots, flying or driverless cars, or space tourism.

As discussed above, this process largely emerged in the early 20th century. We will now look more closely at two particular case studies: first, the internal combustion engine and the petroleum-based socio-technical imaginaries that were built around it, and how these evolved during the course of the century before finally become obsolescent; second, the rise of so-called 'smart' technologies, which are based on identical value systems and represent an almost seamless transition towards post-petroleum imaginaries.

2.1 Case Study 1: Petroleum and the Internal Combustion Engine

The new machines of the late 19th and early 20th century, such as the internal combustion engine or the coal-powered steam generator, revealed for the first time the true potential of fossil fuels. Petroleum, for example, is a naturally occurring liquid that stores a fragment of the solar energy that reached Earth during the Jurassic and Cretaceous periods (typically via algae and woody plants). While the first recorded use of petroleum can be found 4,000 years ago when natural asphalt was used in the walls and towers of Babylon, it was not until the early 20th century that the potential of petrol as a useful form of energy began to exert its influence on so many diverse aspects of human life.

The aeroplanes, automobiles and ships that were built around these engines became the symbols of the new machine age, as extrapolations of the *potential* of the internal combustion engine fed the utopian imaginaries of the near future. For a country emerging out of the despair of the Great Depression, *Streamline Moderne* (as it became known) represented the American dream of freedom and escape. Designers were for the first time beginning to play an instrumental role in linking technological progress to the notion of a better future, all in the service of American corporate capitalism. According to the design curator David A. Hanks, American Art Deco and Streamline Moderne differed from the European functionalism of the Bauhaus in that, while the former 'arose from an artistic vanguard', streamlining was 'aimed at the widest possible public and was based on an admiration for industry and speed' (Hanks & Hoy, 2005).

Source: https://www.flickr.com/photos/x-ray_delta_one/4453386674/in/photostream/

The movement inspired the design of a new wave of domestic products, from toasters and kettles to radios and televisions to children's toys, that would give consumers a sense of buying into – and thus belonging to – the utopian American dream, the 'World of Tomorrow'.

Nothing exemplifies this period of techno-optimism better than *To New Horizons*, the promotional film of designer Norman Bel Geddes' *Futurama* exhibit in General Motors' 'Highways and Horizons' pavilion at the 1939 New York World's Fair. The film begins by invoking 'the mystery and the promise of distant horizons [that] always have called men forward' with the promise of a brighter future; a future driven by technological progress, but one which paradoxically never quite arrives. The imagery accompanying the voiceover is the settlers' view of America, complete with covered wagons and frontier forts: moving West to conquer and colonise new territory as well as the indigenous inhabitants, finding new ways to subjugate nature and apply the logic of extractive capitalism, always enabled by the advent of new technologies. In the film the frontier becomes a network of futuristic highways 'for men to go places', symbolising American freedom and dominance. The film represents perhaps the perfect sociotechnical imaginary, a means to 'engage directly with the ways in which people's hopes and desires for the future – their sense of self and their passion for how things ought to be – get bound up with the hard stuff of past achievements' (Jasanoff, 2015, p.32).

The core message of *To New Horizons* is that this new world is in a constant state of flux, 'opening before us at an ever-accelerating rate of progress' with the related imaginary representing 'a greater world, a better world, a world which always will grow forward.' As the (piston or intermittent) internal combustion engine transitioned to the final 'product' stage of the diagram, new dreams were necessary. In the 1950s the invention of the jet engine (Continuous combustion) allowed for supersonic flight, in turn expanding the horizons and moving the technological dream upwards and into the 'final frontier' of space (note again the colonising terminology).

This provided the impetus for countless new visions including the Moon mission and related Cold War imaginaries (Barbrook, 2007). It also represented the final extrapolation of the petroleum dream, in the sense that within a few years these utopian dreams would be exhausted, deflated. As the novelist J. G. Ballard (1979) observed in an interview titled 'The Space Age Is Over':

> "The world of 'Outer Space', which had hitherto been assumed to be limitless, was being revealed as essentially limited, a vast concourse of essentially similar stars and planets whose exploration was likely to be not only extremely difficult, but also perhaps intrinsically disappointing … The number of astronauts who have gone into orbit after the expenditure of this great ocean of rocket fuel is small to the point of being ludicrous. And that sums it all up. You can't have a real space age from which 99.999 percent of the human race is excluded."

Elsewhere at the same expo in 1964, however, a new genesis was being revealed which introduced a refreshingly new direction for technological futures. The IBM Pavilion, with exhibition design and a film presentation by Charles and Ray Eames and architecture by Eero Saarinen, introduced visitors to the computer and its place in mainstream contemporary life. Again, quoting Ballard (1979), this time on the promise and allure of the Information Age:

> "The ability to pass information around from one point in the globe to another in vast quantities and at stupendous speeds, the ability to process information by fantastically powerful computers, the intrusion of electronic data processing in whatever form into all our lives is far, far more significant than all the rocket launches, all the planetary probes, every footprint or tyre mark on the lunar surface."

2.2 Case Study 2: Smart Futures

Ballard's prophetic observation segues neatly into the second case study: the dream of 'smart'. The term has relatively ancient roots, predating the emergence of computer technology, robotics, and notions of artificial intelligence. In the 19th century, the word 'smart' was used as an adjective to describe someone quick-witted, refined, or elegant. Davin Heckman (2008), in his book on the evolution of the smart home, cites the advertising campaign for the Oldsmobile Futuramic to illustrate the semantic evolution of the term:

> "In the truly modern home or the truly modern car, it's functional design that counts. Smart styling is styling with a purpose, as seen in this 1948 'Futuramic' Oldsmobile. Luxuriously appointed inside and out, the Futuramic Oldsmobile brings truly modern post-war design to the automotive field. There's utility as well as beauty in every smart detail, there's the safety of greater visibility, there's automatic shifting too and no clutch pushing thanks to GM Hydramatic drive. The smart way to go is the Automatic way, in a Futuramic Oldsmobile."

The connection between smart and automation evolved into one of the key STIs of the 20th century. The logic is relatively simple: automation builds on the early promise of modernism, where advances in technology lead to domestic products that reduce the need for human labour and increase notions of comfort and leisure in everyday life. The emerging technology behind these new imaginaries was the computer – the important advances made during WWII, in particular at Bletchley Park on encryption, had highlighted the vast potential of this technology, and research continued post-war with new impetus. In 1948, Norbert Wiener published *Cybernetics or Control and Communication in the Animal and the Machine*, which described how the function of machines and living organisms were governed by the same laws (feedback loops). What emerged from this scientific research was the notion of self-regulating thinking machines that would soon be used to generate, plan and control environments. Whilst research in the military domain continued in the background, in the foreground new imaginaries were flourishing, especially in the fields of transportation and the domestic – here with a strong focus on the kitchen.

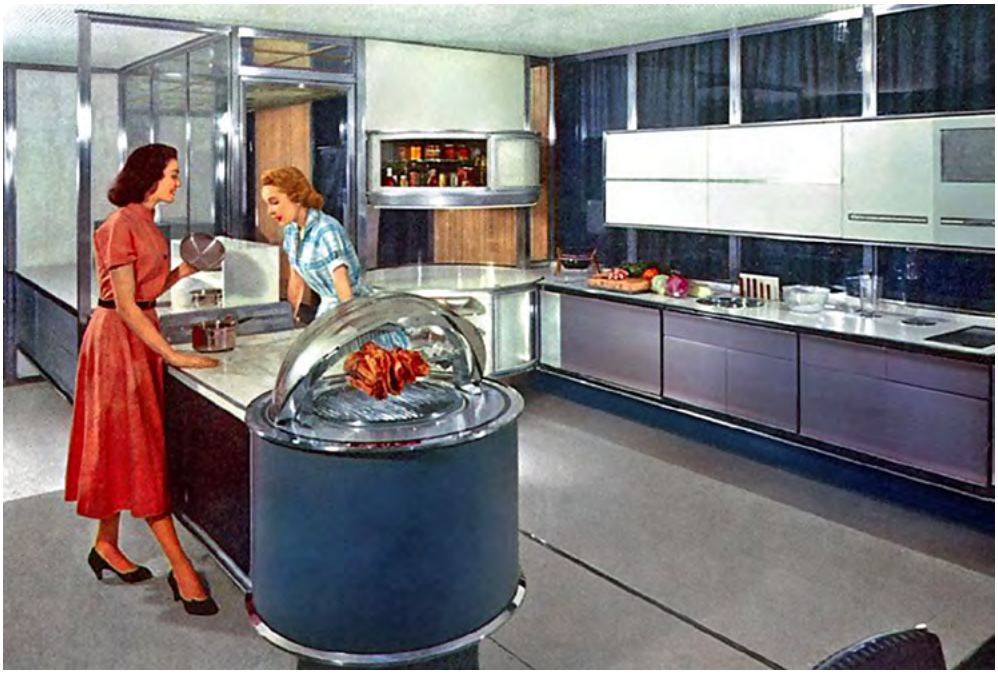

Figure 4. Frigidaire prototype kitchen (1957). By James Vaughan, 2009, Flickr. Source: https://www.flickr.com/photos/x-ray_delta_one/4189652500/in/photostream/. CC BY-NC-SA 2.0 DEED.

1950s *kitchens of the future* were not yet classified as 'smart', yet they represent the evolution of the dream that continues to this day. For example, RCA and Whirlpool's 'Miracle Kitchen' began travelling around the world in 1956 and made an appearance at the American National Exhibition in Moscow in 1959. It was meant to showcase a future where everything was controlled with the push of a button, so that 'the things

women don't like to do are done automatically', according to a promotional video for the concept kitchen. As Anya Smirnova, curatorial assistant at the London Design Museum, explains: 'the features of the kitchen, like the autonomous vacuum cleaner, anticipated today's domestic robots and smart home devices. As a pre-history of the contemporary smart home, the RCA-Whirlpool Miracle Kitchen provides important historical context' (Whirlpool, 2018).

As in the case of petroleum dreams, the imaginary continued to evolve, informed by the latest developments in computer technology. In the 1980s, for example, the American entertainment industry began to adopt a global approach to technological planning, best exemplified by Walt Disney's Experimental Prototype Community of Tomorrow (EPCOT). More than just a theme park, EPCOT was described as:

> "A community of tomorrow that will never be completed but will always be introducing and testing and demonstrating new materials and new systems. And EPCOT will always be a showcase to the world for the ingenuity and imagination of American free enterprise." (Beard, 1982)

As a highly planned, controlled and automated 'living blueprint', EPCOT is a vision that heralded and contributed to the future global spread of automated systems in everyday life – described in a language that could have been taken almost directly from *To New Horizons.*

In the late 20th century, the computer completed the shift from the fields of research, military, and business to the homes and domestic lives of many people. However, whereas the normalisation of the motorcar led to the end of petroleum dreams, computer-related dreams continue to flourish, fed by various concepts such as Ubiquitous Computing (Weiser, 1991), Augmented Reality (Caudell & Mizell, 1992), the Internet of Things (Ashton, 1999 / 2009) and Artificial Intelligence (Turing, 1950)[1], and through marketing and branding exercises such as LG's 'HomeChat' (2014) and the Ericsson 'Social Web of Things' (2012). The fundamental challenge with future smartness relates to the ever-diminishing number of acts left to be automated. Bill McKibben in his aptly titled book *Enough* (2004) provides the following examples of how the industry was thinking in the early 2000s:

> "Eventually, says Mary Walker, of IBM's home automation division, 'smart ID' chips will be implanted inside you. Then 'your body temperature might give your stereo system cues as to your mood and it would select appropriate music'; the chip could also 'compute how much of your body weight is fat, and offer suggestions for diet recipes to the refrigerator'." (McKibben, 2004, p.121)

In the early twentieth century Sigmund Freud wrote about the pleasure principle (id) versus the reality principle (ego), the latter involving the delayed gratification that comes with adulthood. As science fiction has played on numerous times in recent decades (think of Disney's own *WALL-E*), 'smart' technologies – higher level automation combined with late capitalism – often invite us to override our adult selves, exchanging self-control and responsibility for the childish expectation of instant gratification in all aspects of daily life.

3. Five Insights: Why Visions of the Future Have Stagnated

In our present century, the future has become highly complex and contested. While Silicon Valley continues to present aggrandised versions of 20th-century techno-utopias[2], some observers have begun to

[1] AI could be described as a recuring dream having passed through numerous iterations since its genesis in the 1940s

[2] See, for example, Elon Musk's recent announcements for his Neuralink – the longer-term goal for this research is human / AI symbiosis.

'comprehend that we live in a world that is taking away futures for ourselves and non-human others' (Fry, 2020). Berardi (2011) described the 'slow cancellation of the future' as a consequence of diminishing trust in the scientists and policy-makers who once exercised the kind of powers that made the Moon programme possible (exemplified by John F. Kennedy's speech at Rice University in 1962). Speculative designers have also been guilty of focusing too much on the technological future, albeit for more responsible ends. As Matt Ward points out: 'By focusing on futures … many believe that SCD [speculative and critical design] neglects the near and direct urgency of now' (Mitrović et al., 2021, p.185).

To reflect more broadly on the implications of the two case studies outlined above, we present five key observations on why visions of the future have stagnated or are simply not appropriate for the world of the 21st century, and why they are ripe to be revaluated and reappropriated using new design approaches.

1. **Those responsible for the creation of future visions are guilty of being overly optimistic, never acknowledging the possible negative implications of their dreams.**
   The constraint of positivity – what we might call 'progress dogma' – blinds future-makers and future-shapers (scientists, technologists, politicians, designers) from the potential negative implications of their proposals. Technology is good, the story of progress goes, and the future, as long as technology takes the lead, will be better than the present. This blind optimism and faith in technology is not limited to mere visions, either: it extends to designed artefacts such as the Amazon Echo, which bring with them into peoples' homes a host of unintended consequences.

2. **Those responsible for the creation of future visions are guilty of being overly simplistic – perfect worlds, perfect people, interacting perfectly – thus negating the complex and messy reality of human lives.**
   In advertisements for smart homes and smart products, the generic user is overwhelmingly young, able-bodied, and wealthy. He is often male, usually white, and heterosexual, a bachelor in a perfect luxury apartment of glass and steel. Advertisements for the LG 'HomeChat' (2014) or the Ericsson 'Social Web of Things' (2012) are two examples. Strengers (2014) has called one version of this idealised user 'Resource Man': 'a rational, individual, and masculine image of the energy consumer'. In contrast, what would a smart home for a multi-generation family look like – unharmonious, not necessarily wealthy, and full of complicated interactions? Or a smart home that favours connections to natural systems over technical systems?

3. **The reduction of technological dreams into singular experiences has resulted in the dislocation of means from ends – the systems (means) that facilitate the function of future artefacts (ends) are inherently complicated and restrictive.**
   Take, for example, the automated vehicle. Whilst the dream of a car that drives itself is relatively easy to imagine, its realisation is constrained by (amongst other things) the complexity of engineering and computation, legacy infrastructure, insurance laws, and road legislation. The dream is simple, reality is complex. Dreams represent a jump to another reality; socio-technical change is iterative for a reason. Dreams, in this sense, can provide future goals to aim for – but short-term time-frames constrain the political and corporate actors who have the power to act upon the social and the technical (for example through the need for near-future shareholder satisfaction or fixed-term democratic government). How then can dreams lead to systemic change in the context of everyday life?

4. **The reduction of visions into objects of desire leads to an increased instrumentalisation of operation and banal iterative development.**
   The motorcar again: travel has become instrumentalised as we focus on the object, rather than the act. Since the beginning of the 20th century, the car has iterated in small steps made possible by technological advances. Why is this a problem? Because it constrains designers to design only what the product could conceivably evolve into – narrowing the scope of future possibilities. Smart products, such as the automated vehicle, are simply existing products updated with sensors and computation. How can we step outside of the constraints of this sort of lineage to design more radical and appropriate solutions – not influenced by history?

5. **Many of the metrics through which we evaluate future imaginaries remain the same as those from the machine age – faster, more efficient, more automated – and as such are wholly inadequate for addressing the complex problems we face today.**
   In the first point of his influential 'ten principles', German designer Dieter Rams (n.d.) states simply that 'Good design is innovative', elaborating that 'Technological development is always offering new opportunities for innovative design.' But while 'new opportunities' are still being offered by emerging technologies, the straightforward exploitation of these opportunities has become complicated in our own time by a growing awareness of the impact we are having on the planet. The faith in technological enhancement expressed in Apple's early (1990) slogan – 'The power to be your best' – is no longer sufficient to meet humanity's complex needs. Rams' list does include the advice to keep 'physical and visual pollution' to a minimum, but it fails to acknowledge the larger extent to which design is implicated in or even responsible for catastrophes such as global warming.

4. New Dreams: The Promise of Speculative Design

'How, Taylor asks in the opening pages of *Modern Social Imaginaries*' – as Jasanoff (2015) writes – 'did modernity come about, with its distinctive complex of new practices and institutions, new ways of living, and new forms of malaise? His explanation can be summed up in two words: imaginaries changed.' At the turn of the last century modernism brought about a fundamental change in the socio-technical imaginary, facilitating an unchecked approach to the future driven by a fundamental belief in the positive progress of technology.

How then, can we develop approaches that change the current imaginary? And more importantly, what roles could designers play in this process? As a starting point, we present three ongoing speculative design projects by PhD students. Speculative design in this case denotes a type of experimental design practice that explores imaginary futures or alternative presents through the use of 'objects and images': for example, 'how domestic spaces change with the evolution of new communication technologies; how relationships shift under surveillance capitalism; … how work will be reconstituted through automation', and so on (Mitrović et al., 2021, p.168). More specifically, each of these three projects acts in a different phase of the tripartite process described in the 'journey' diagram (Figure 1): first, placing the designer in the laboratory to upstream prototype and infuse scientific research with social responsibility and/or domestic sensibilities; second, revisiting stagnant technological dreams and updating through the counterfactual history approach (Auger & Hanna, 2023); and third, downstream 'super testing' using speculative methods to better understand the implications of technologies in everyday life.

1. Placing the designer in the laboratory to upstream prototype and infuse scientific research with social responsibility and/or domestic sensibilities.

The transition towards a post-petroleum society is one of the main challenges addressed by a wide range of actors (activists, researchers, industrialists, designers, politicians, and consumers). Each vantage point or knowledge-base creates and feeds a different imaginary – a dream that is social, economic, or scientific in character. (This links to insight 4 above: interrogating and rethinking notions of materiality at the inception of the design, de-objectified and free from the outset.)

One effect of a post-petroleum shift that exerts a strong impact on industrial design, and on industries more widely, is the inability to create new petrochemical-sourced plastics. Time has shown that the discourse around sustainability and ecological thinking has not led to a substantial reduction in the production of plastics. This reluctance to slow or reverse consumption highlights the techno-solutionist position of industry – waiting for a scientific revolution that will lead to a new material paradigm.

Figure 5. Images from the project *Flower*: Long natural flax fibers are broken into shorter ones to be integrated as matrix inside a composite material.

Historically, such a rapid and drastic paradigm shift in industrial materials already occurred when plastics became the new standard. First used to replace animal-based material such as horn and ivory, plastics developed rapidly after WWII aided by military research and funding. Unlike any other material, its 'plastic' qualities were so extensive that it gave designers previously unimaginable freedom in terms of shape, colour, and performance. In this sense, plastic was a new horizon of infinite possibility, matching the desire of the post-war period for a bright and colourful future. Plastic was a 'superlative material' whose praises were sung even by poets like Raymond Queneau in *Le Chant du Styrène* (1958), a short documentary directed by Alain Resnais for the industrial giant Pechiney.

Today the view of plastics is far less optimistic. Plastic has become a major threat because of the pollution created during its production, its lack of effective recycling, and its degradation into microplastics that poison living organisms. The pressure of public opinion, taxes, and legislation on manufacturers has not made them change their practices so much as forced them to invest and transfer this pressure into the research field, waiting for a miraculous technological solution. We may be again at the dawn of a new materials paradigm shift, but this time it is a more complex and globalised world deeply rooted in consumption. To question the role of design in this transitory moment and speculate on the evolution of industrial objects, Axelos has chosen to focus on material research, working together with scientists at the Institut national de la recherche agronomique (INRAE).

At the beginning of this expected shift, materials are still quite weak in terms of performance, plasticity, and the shaping process. Low-tech experiments are already ongoing, especially in independent design studios, along with more technical materials and process-related experiments currently in development in laboratories. As designers, we can only speculate on new 'potential materials'. This immateriality and potentiality of future matter radically alter the design process, which is normally involved in the late stages of technical projects. Traditionally, designers can experiment with industrial materials if they are stable enough, with a fully developed manufacturing process already available. This exploration process shapes

the materiality of those designed objects. But how can designers experience the materiality of a material that has not yet been created? 'Potential matter' forces designers to rethink their position in the project timeline, to adapt and develop new methodologies and approaches regarding material-centred design, and to create new interactions with those involved in this early stage of development, especially researchers. By collaborating with active researchers and placing the designer in the laboratory, this practice-based PhD will offer the opportunity to experiment with new methodologies and document impacts on both design and research practices.

2. Revisiting stagnant technological dreams and updating through the counterfactual history approach (Auger & Hanna, 2023).

Valentin Graillat's project *Archaic Smartness* uses the counterfactual history approach to question and update stagnant smart home visions of the future. (This links to insights 2 and 3 above: reimagining 'smart' as something that goes beyond an instrumentalist focus on 'solving' human problems with technology to acknowledge complex ecosystems; the home is not simply the end, but a system of means and ends functioning in harmony with the local environment.) The project began by tracing the actual history of the smart home to identify the key moments[3] (political, cultural, technological, corporate, etc.) that led to the contemporary situation. The genesis of the smart home was traced to the *Houses of Tomorrow*, conceived in the United States during the Cold War by the hegemonic corporations of the time (Disney, Monsanto, General Electric). These seductive and spectacular future visions conditioned long-term expectations in the West by positioning as desirable a technology-driven lifestyle centred on consumption, disengagement, and entertainment. The legacy of yesterday's *Houses of Tomorrow* is the crystallisation of the desire for market-friendly technological futures constructed through a value system based on the application of smart technologies (as discussed above). The counterfactual approach acts to challenge this dominant and entrenched model through the generation of alternative narratives and imaginaries that bypass the constraints of historical lineages.

After tracing a timeline of the smart home concept, Graillat identified key historical events where a different outcome could have led to an *alternative present* more in line with current concerns for the environment and sustainable lifestyles. The project's counterfactual moment came in 1973 when the United States was violently shaken by the oil crisis. President Nixon signed the Independence Project and intended to initiate a strategic policy to develop domestic energy production. The counterfactual history postulates a radical alternative research group, similar to the Farallones Institute in Berkeley, receiving substantial government support facilitating the rise of an alternative path in which the term 'smart' bifurcates from a market-friendly automated culture towards one more symbiotically aligned with natural systems and habitats.

The practice-based element of the project speculates on various research outputs of a fictitious scientific institute based in California, presented through a variety of *historical evidence*, including blueprints, books, and models that would have been displayed at trade fairs and public exhibitions. These combine to present historical visions of an alternative future which acts as a manifesto – the term 'smart' no longer refers to house *automation* but instead to the *adaptation* of the home to its local living environment (such as approaches to materials and the production of bio-energy). The first concept imagines a radical form of cohabitation with local organisms through the development of vast termite colonies alongside the human home – this symbiotic relationship provides security for the termites and biogas for the human inhabitants.

[3] The Farallones Institute was a non-profit, educational organisation dedicated to the research, development, demonstration, and application of potentially appropriate community technologies. All their programs and projects placed an emphasis on the integrated nature of renewable sources of energy, land and resource planning, water and waste, recovery systems, and food production within the context of cultural and social acceptability, and local community self-reliance.

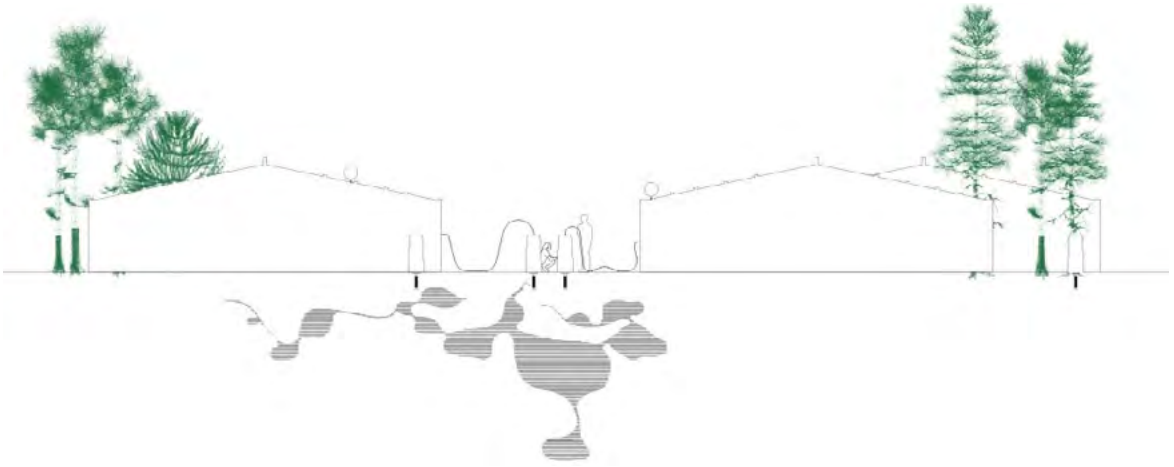

Figure 6. Habitat-scale domestication of termites to produce small quantities of biogas for food and lighting.

The counterfactual approach provides the designer with the opportunity to continue the evolution of the alternative timeline which becomes increasingly diverse as more time passes, offering the designer a 'rich narrative potential for reimagining and critiquing technological developments and contemporary products' (Auger, 2012).

3. Downstream 'super testing' using speculative methods to better understand the implications of technologies in everyday life.

The super-testing method operates as a crash test of future visions, public policies, services, and products enabled through speculative design methods. As practised by Estelle Hary, investigating the ramifications of AI and machine learning in public services, super-testing prompts the involved publics to identify and assess potential implications and externalities that may arise from the proposed speculative artefacts. (This links to insight 1 above: casting a cold eye on 'progress dogma' to explore possible consequences, negative as well as positive, when research enters the real world and takes shape as concrete products and policies.)

Super-testing aims to challenge dominant socio-technical imaginaries by changing the lens through which a particular issue is considered. It highlights issues that are often overlooked due to prioritisation of economic values such as efficiency and productivity – for example with the deployment of AI systems in public services. Indeed, as Hary identified through her research, a well-known narrative, conveyed through various institutional means (reports, public funding programs), underlies the deployment of AI in French public services: the technology is thought to be impartial and effective. It can handle vast amounts of information quickly and might potentially lead to automated decision-making, speeding up administrative processes. This would free up time for public servants to undertake more valuable tasks. The promise goes even further by suggesting a vision where public services would be customised to individuals' needs. In essence, AI systems are presented as a cost-effective magic wand, capable of solving the State's biggest (political) challenges while improving the quality of public services.

As with many such promises, however, blind spots and preconceived ideas are widespread. Promises based on AI systems do not take into account the body of literature on political, environmental, and social justice issues that come with their use. They also rely on the assumption that the economic, political, social, and material conditions of society are immutable. For example, projects to deploy AI in public services are conceived as if future societies will benefit from the same material conditions as today when the energy and raw materials needed to maintain the infrastructure required for AI systems to run are still relatively abundant. But what happens when such material conditions can no longer be met, while all public services

have been digitised, 'algorithmised', and 'AI-ified'? This possibility has been explored through the Fail-Soft[4] mode in a degraded world scenario where several design artefacts suggest the intermittent availability of public services based on energy resources. A billboard at a bus stop displays the weather forecast of digital public services. Some of them are suspended, others are running normally, while still others run on a backup based on citizen mobilisation. To face the new material conditions of this scenario, the government has created the National Authority for Administrative Transparency, in charge of reviewing new projects aiming to deploy algorithms in public services based on environmental criteria.

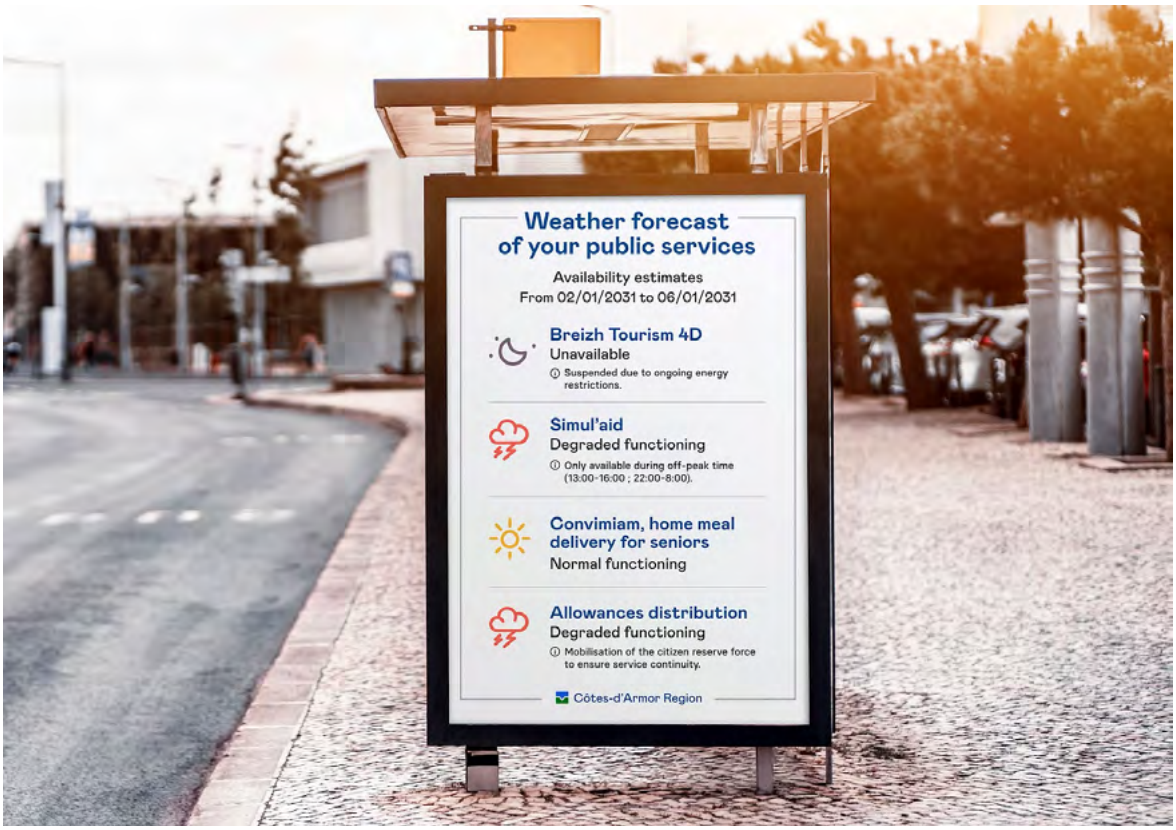

Figure 7. Speculative government information services at bus stops providing updates on the state of public services.

These artefacts raise many questions. How was the priority given to each public service decided, and who took part in this decision? Who reviews the applications for new algorithms and learning systems to be implemented? How was the criteria grid built? Why are such projects still supported when the world does not seem able to sustain them? Super-testing does not stop at the creation of speculative design artefacts that raise provocative questions about the shortcomings of technological promises. For the 'test' to happen, the design artefacts need to be confronted with the stakeholder publics: policymakers, public servants, citizens, civil society, unions. The design of the 'debate space' is in that regard also part of the super-testing method, where supporting the diversity of people taking part in the debate is critical to express a plurality of views coming from everyone's personal experiences. It enables a rich, detailed, and diversified mapping of the positive and negative externalities around a technological dream whose analysis might allow for an update of our collective vision of our future society. This in turn might lead to the adaptation, bifurcation, or even cancellation of public policies around AI and other smart systems.

[4] A Fail Soft System is one that shuts down non-essential functions when something goes wrong allowing the system to function at a basic level. The term can be applied to machines, vehicles, computer systems, other systems, and many types of equipment.

5. Conclusions

Following the SpeculativeEdu project conclusions, we aim to contribute to the dialogue on speculative design by contemplating 'a plurality of futures beyond the techno-heroic' and more importantly, 'reclaim[ing] the present' through 'speculat[ing] on different versions of today' (Mitrović et al., 2021, p.211). Design needs a revolution in order to keep pace and adapt to the rapidly shifting demands (social, political, ecological) of the 21st century. (This links to insight 5: the need for new metrics to reflect complex new 21st-century realities.) As Papanek (2019) suggests, we must learn from disaster. This revolution must begin in design education, and one way to bring it about is to create new approaches that are both speculative and pragmatic, linking alternative visions to urgently needed actions in the real world. Speculative design must abandon the simplistic and slavish game of extrapolating futures based largely on emerging technologies, and instead examine existing (and historical) conditions in order to imagine alternative presents, more appropriate futures - other ways of being.

At the beginning of this paper we traced the journey of a technology through a tripartite process, from the laboratory to the dream phase to the products and services of daily life, and examined the role design plays in this process. To illustrate this journey, focusing in particular on the dream or imaginary phase, we presented two case studies: petroleum and the internal combustion engine, and 'smart' technologies. In the next part we presented five insights to explain some of the reasons why visions of the future have stagnated. Then in the last part we presented the ongoing work of three PhD students, each of whom is focusing on a different stage of the journey – the designer upstream in the lab; the designer revisiting stagnant technological dreams; the designer 'super-testing' downstream in everyday life – and the different role design could play in each stage as a means of creating new visions and approaches that are better suited to the huge challenges we face in the 21st century.

We have tried to raise questions and introduce new possibilities to provoke changes in design education. What is the role of dreaming in design? How conscious are we of the dreams that shape our futures? What happens when technological dreams become repetitive and stale? How do our dreams relate to our waking lives, to practical necessities and urgent responsibilities? Should we stop dreaming about far-off futures and magic solutions, and wake up to the realities of our present? How can we dream differently, and actively, so that our dreams help us imagine and shape better realities? There are still many questions to investigate – many alternatives to imagine – and urgently. In the words of Ursula K. Le Guin (1979), 'it is above all by the imagination that we achieve perception, compassion, and hope' (p.53).

About the Authors:

James Auger is the director of the department of design at the École normale supérieure Paris-Saclay (ENS) and co-director of the Centre de Recherche en Design, a laboratory jointly run by ENS and ENSCI Les Ateliers.

Julian Hanna is associate professor of Culture Studies at Tilburg University. His research focuses on critical intersections between culture, politics, and technology. His forthcoming book, Island, will be published as part of Bloomsbury's Object Lessons series in September 2024.

Valentin Graillat is a PhD design student at ENS Paris-Saclay. He is currently conducting a practice-based thesis that investigates the role of technological dreams and past-future imaginaries through the concept of the smart-homes.

Etienne Axelos is a PhD candidate at the Centre de recherche en design. By extracting industrial techniques from their context to human scale, he seeks to challenge contemporary practices of consumption, use and the production of industrial objects.

Estelle Hary is a PhD candidate at RMIT Europe. She examines applications of AI in the public sector to facilitate better transparency and fairness. She co-founded the design studio Design Friction which uses design fiction methods to guide public policies.

KEYWORDS | SPECULATIVE DESIGN, POST SPECULATIVE, MARGINALIZED FUTURES, JUGAAD

ABSTRACT | Detroit is at a pivotal moment, facing a transformation that could redefine its identity. Historically known as the powerhouse of American industry, the city has endured economic challenges, demographic shifts, and changing urban dynamics. Recently, a narrative of rebirth through tech innovation and urban redevelopment has gained traction, promising modernization but risking the displacement of established communities and marginalization of their voices. Parallel to this narrative, grassroots movements, local organizations, and individuals envision a Detroit prioritizing equity, resilience, and communal well-being. They advocate for inclusive growth that respects and incorporates Detroit's diverse communities rather than erasing them. However, there's a noticeable absence of young voices in these crucial conversations about the city's future, a gap that needs bridging to ensure Detroit reflects its youth's aspirations and identities. The workshop aims to fill that gap, providing a space for collaborative dreaming and participatory planning. It challenges existing power structures by fostering alternative visions for Detroit. This article delves into the innovative intersection of post-speculative & critical design (POST-SCD) and the critical jugaad paradigm through the lens of the transformative workshop in Detroit. The methodology provides the much-needed inclusive and democratizing approach to design methods that encourages participants, especially the youth, to actively shape their city's future, leveraging their insights and dreams to forge new paths.

1. Introduction

This article delves into the innovative intersection of post-speculative & critical design, also used here as post-SCD and the critical jugaad paradigm through the lens of a transformative workshop in Detroit. As the city grapples with narratives rooted in technology-driven progress and community gentrification, the workshop emerged as a catalyst for change, empowering Detroit's younger generation to shape their city's future narratives actively.

The workshop, firmly grounded in abolition principles, introduced participants to the critical jugaad framework, where jugaad represents the art of resourceful problem-solving and creative improvisation. The amalgamation of these two paradigms allowed participants to reframe the dismantling of oppressive systems as an opportunity for constructing just and equitable alternatives—a notion at the core of critical jugaad thinking. A pivotal aspect of the workshop was its emphasis on moving beyond critique and into constructive action. Participants explored applying critical jugaad principles to address systemic inequalities and transform their city. Through the participatory speculation process, attendees actively co-created alternative futures for Detroit, positioning themselves as proactive agents of change and reflecting on how they could apply critical jugaad principles to address systemic inequalities and transform their city.

This article also explores the post-speculative design and the critical jugaad paradigm to propose diverse ways of envisaging and forming equitable futures in urban development and community empowerment. These structures seek to break the norm, not just by mere speculation or critique, but rather by proposing a move to be more action-oriented through this inclusive methodology. The post speculative & critical design or post-SCD looks up to traditional design thinking. It underscores the necessity of actual interventions and applications in the real world, not just mere speculation or deconstructive criticism. It does not dismiss the fact that imagining and speculating are vital in imagining alternative futures but rather insists that these should be rooted in practical, implementable strategies. Another derivation is the critical jugaad paradigm from the Indian term “jugaad,” which is said to apply frugal innovations, usually with modest resources but of flexible and intuitive ingenuity. Unlike the traditional jugaad, which has the characteristic of application under the existing constraints and without an inquiry into more systemic or deep-rooted problems, this critical jugaad paradigm becomes critical on its own. This means it encourages creative problem-solving and serves as a stimulant toward deep analysis of social, economic, and political systems that perpetuate inequity. The addition of critical analysis to the principles of jugaad makes it a creative way for communities to address systemic injustice while continuing to advocate for resourcefulness.

The workshop's unique perspective on the "politics of imagining futures," as inspired by Gerber's work (2018), was enriched by the critical jugaad paradigm (Butoliya, 2016). It showcases how the workshop created a dynamic environment where participants could harness their resourcefulness to shape Detroit's future narratives with a focus on equity, resilience, and community-driven solutions.

The article underscores the significance of incorporating grassroots organizations, local insights, and the voices of Detroit's youth throughout the research process, demonstrating how critical jugaad principles enhanced the workshop's problem-solving capacity and encouraged innovative, adaptive solutions. As an outcome of this workshop, the article offers insights into the methodologies and tools used to empower participants through the fusion of post-speculative & critical design (post-SCD) and the critical jugaad paradigm. It illustrates the critical role of research that integrates these paradigms in advancing the cause of abolition, particularly in addressing the complex challenges of urban transformation. It exemplifies how synthesizing critical jugaad principles and grassroots participation can drive innovative, socially just, and equitable futures for Detroit and beyond.

2. Theoretical Framework

2.1 Post Speculative & Critical Design

Many design schools worldwide have incorporated speculative and critical design or SCD practice into their curricula. Students sometimes engage with speculative design projects to enhance their portfolios. However, with this new phase of SCD, no significant change has been noticed yet in its practice or pedagogy. Students and designers have produced and imitated similar artifacts and projects from other contexts, and the counter-critiques are not reflected in their works. The new academic programs in SCD follow similar paths and continue reinforcing the prevalent dichotomy and hegemony of Western influence on this practice in most cases. There is a need for design practice in response to the mainstream SCD practice that will promote the debates essential to the public reception of such design practice and support pluralistic visions.

There is an imperative to address the underlying issues and to generate and explore a renewed framework for speculative and critical design practice. This raises many questions, the most prominent being: what is post-critical in design? The term post-critical (sometimes used as postcritical) was first used by Michael Polanyi in his seminal work Tacit Knowledge: Towards a Personal Philosophy (1998), which meant a shift away from objective scientific thinking or critical thinking to thinking that considers personal tacit knowledge (Polanyi, 1998). Post-critical design emerges as a response to critiques of the critical design practice, which has been influential in highlighting design work's social, political, and ethical dimensions. Critical design, as discussed by authors like Malpass (2017) and Bardzell & Bardzell (2013), operates as an interrogative and discursive practice, using design as a medium to question and challenge norms, values, and assumptions embedded in contemporary culture and technology.

The post-speculative design could be seen as an evolution or a critique of speculative design practice. While there is no hard definition or a set of practices that define post-speculative design universally, it probably builds off or responds to the methodologies and aims of speculative design. The speculative design itself produces imaginative projections of alternate presents and possible futures through design representations and design objects.

> "It sometimes gets serious, sometimes playful; it provides a way to think about futures and critique current practices through designed artefacts that involve the spectators in the scenarios of futures." (Auger, 2013)

An instance of such projects is works such as "Speculative Everything" by Dunne and Raby, where design is considered as a tool to imagine how things might be and propose a kind of design that creates ideas rather than objects, opening debate about the kinds of futures people want (Dunne & Raby, 2013). The overview of speculative design pedagogy and practice has been well researched and documented by the Speculativeedu project and documented in the resulting manuscript Beyond Speculative Design: Past Present Future (Mitrović et al.,2021). This gives a deep understanding of how post-speculative design could be understood.

Post-speculative & critical design evolves beyond speculative and critical design (SCD) by critically examining its principles and extending its outcomes. It questions SCD’s approaches and explores new methods and results that engage more directly with current issues and prospects. It integrates marginalized voices to foster equitable futures by focusing on actionable, inclusive outcomes and addressing socio-political concerns. Unlike speculative design, which imagines future possibilities and critiques present practices through artifacts and scenarios, post-speculative & critical design advances into actionable, participatory, and interventionist approaches. It emphasizes stakeholder co-creation, confronts societal and environmental challenges, and tests future speculations in real-world settings. The post-speculative & critical design merges speculation and critique with practical implementation, aiming to actively shape future realities.

2.2 Critical Jugaad

To acknowledge the wide range of making practices that emerge from conditions of scarcity, a recent study explores the concept of "jugaad" – a term from the Hindi language that encapsulates making do and surviving despite limited resources. While often viewed simplistically as a make-do solution involving found objects, this practice transcends limitations in its native context. Jugaad represents a mindset, a form of critical yet collective thinking that serves as an informal yet legitimate way of life in societies where resources are scarce, particularly for marginalized groups. Despite its innovative approach, this form of creativity has historically been overlooked as a designerly practice, primarily because it challenges the Western colonial foundations of design. The study posits an urgent need to disrupt Eurocentric design narratives by embracing pluriversal perspectives that value diverse cultural viewpoints.

The research introduces the term “critical jugaad” (Butoliya, 2016;2017) as a method to decolonize design through various modes of representation, discourse, and practice, particularly at the intersection of Global South perspectives and critical design. Critical design, a field known for questioning social and cultural norms through artifact creation, has been critiqued for its Eurocentric and privileged stance. The author argues for a shift beyond the Western logic of criticality in design, advocating for a “critical jugaad” approach that reflects the complex social, cultural, political, and economic realities of marginalized communities in the Global South.

Global South extends beyond geographical boundaries, representing communities historically marginalized by colonization, globalization, and capitalism. Detroit, Michigan, serves as a notable example within the United States, a country typically associated with Western privilege. Historically overlooked by the design community, Detroit's designation as a UNESCO City of Design challenges this narrative, emphasizing the need for diversity, equity, and inclusion by studying and establishing locally rooted design and making practices. These practices highlight an inclusive future for such communities and contribute to achieving racial justice by design.

Jugaad is creativity born out of the dire necessity of a society where resources are scarce. It has been a practice deep-rooted within the common people of the Global South and the other marginalized communities, which it carries along with the spirit of resilience and resistance. Critical jugaad, on the other hand, does not relate to making do in the spirit of something ad hoc but, in fact, to redefining the rules set by an environment of severe resource constraint. It is based on local knowledge and takes the form of an improvisation that is sustainable, accessible, subversive, and relevant in its context. Our research in jugaad practices in the context of marginalized communities in Detroit has found that critical jugaad is a vehicle for building community resilience.

The critical synergy in this regard—of abolitionist thinking and critical jugaad in design for social justice—thus lies in the forces of empowerment and equity evoked through systemic change that both efforts are bound to. When the thinking of abolitionist commitment to undoing oppressive systems is combined with the innovative and resourceful tendencies of jugaad in design, the designer's solutions will have served two.

2.3 Synergies between Post-Speculative & Critical Design and Abolitionist Futures

Abolitionist futures envision a society free from prisons, policing, and traditional punitive justice, inspired by past movements seeking to end slavery. This vision focuses on tackling the root issues that lead to harm by empowering communities to create their solutions, utilizing restorative methods, and boosting social support instead of relying on imprisonment. It promotes widespread changes that involve reducing prison populations, championing economic and social rights, and adopting transformative ways of dealing with conflict that mend and strengthen community bonds. The aim is to shift the concept of safety from one grounded in monitoring and discipline to one built on community support, economic possibilities, and collective well-being. Policy changes are necessary to make abolitionist futures a reality, along with growing public understanding, empowering local communities, and collaborating across different societal

sectors. This is all in pursuit of a societal transformation that embraces fairer, more inclusive, and more effective approaches to fostering safety and justice.

Abolition in design seeks to understand how design may play towards visioning and making conditions for the abolition democracy in designing abolitionist futures. DelSesto writes.

> "Abolitionist perspectives have important contributions to make to this emerging work in design, especially in terms of how design thinking and acting might be oriented towards systemic transformation and a renewed social imagination." (DelSesto, 2023, p.257)

The approach at the intersection of abolitionism and design draws a reflection pathway about the existing design practices that might perpetuate or challenge current dominant power structures and bring the design outcomes toward more just and equitable directions.

This workshop delved into various facets of post-speculative design, exploring its potential to foster inclusive, equitable, and radical systemic changes. This critical approach highlights the urgent need to utilize speculative design as a tool to confront and dismantle racial and class-based disparities. By prioritizing the Black experience, these projects critique existing inequities and propose abolitionist futures where such disparities are eradicated. The work underscores the transformative potential of post-speculative design in reimagining societal norms and structures, advocating for an equitable and just future for all, particularly marginalized communities.

Afrofuturism's role within speculative design is pivotal, offering a framework that decentralizes traditional power structures and promotes design as a community-centric endeavor. This perspective is vital for marginalized groups, as it validates and centers black and brown lived experiences within the design process, aiming for inherently equity-driven outcomes (Bray & Harrington, 2021). By foregrounding the experiences and aspirations of these communities, Afrofuturism within speculative design acts as a catalyst for envisioning and crafting futures that are inclusive, equitable, and reflective of diverse societal needs and desires. The application of speculative design in participatory approaches to reimagining community safety exemplifies its potential to instigate profound societal change. By involving community members in envisioning alternatives to traditional policing, speculative design merges with participatory processes to challenge and rethink oppressive systems. This approach provokes thought and encourages collective imagination towards radical systemic reforms, demonstrating speculative design's capacity to empower communities to shape their futures (Gerber, 2018).

2.4 Speculative Co-Design with Marginalized Groups

Engaging marginalized groups in speculative co-design processes is crucial for ensuring that future visions are inclusive and relevant. This approach allows these communities to express their unique perspectives and desires, encompassing utopian aspirations and recognizing ongoing dystopian realities. Through speculative co-design, marginalized voices are not only heard but are integral to the conceptualization and design of future technologies and ideas, ensuring that the outcomes are genuinely inclusive and responsive to the needs of all community members (Harrington & Dillahunt, 2021).

By integrating abolitionist ideas and engaging marginalized groups in co-design processes, speculative and critical design holds the potential to critique the present and constructively shape the future. As we continue to explore and expand the boundaries of SCD, it remains imperative to center the experiences and aspirations of those who have been historically marginalized, ensuring that the futures we envision are truly reflective of a diverse and equitable society.

3. The Detroit Workshop: A Case Study

3.1 Introduction

The workshop titled “Making Just Futures for Detroit (2021)” focuses on imagining futures for Detroit as a city and as a community through the vision of Detroit's youth and the lens of Abolitionist principles. This workshop served as an experimental ground for merging the critical jugaad paradigm with abolitionist design principles, aiming to address the city's long-standing issues of inequality and disenfranchisement. Organized as a collaborative initiative, the workshop brought together local youths, designers, activists, and academics to reimagine Detroit's urban future through participatory future envisioning sessions. Participants were introduced to various design methodologies and speculative tools and encouraged to draw upon their experiences and community knowledge. The workshop facilitated a space where creative problem-solving was not just about addressing immediate needs but envisioning long-term, sustainable changes to the urban fabric of Detroit. Projects developed during the workshop ranged from community gardens that served as social gatherings and education hubs to digital platforms designed to enhance local economies and foster skill-sharing among residents. The case study section will provide a detailed analysis of these projects, exploring how they reflect the integration of critical jugaad and abolitionist principles. It will examine the impact of these projects on participants and the wider community, including challenges faced in their implementation and the potential for scalability.

The workshop was integrated into ongoing research for a studio inquiry of a master of the design program at a research-oriented public university in the United States. The MDES students of the 2020-2022 cohort were the design student participants, with one male and four female students of diverse backgrounds in terms of geographic locations of their hometowns and ethnicities. The community participants were one founder and four youth members of the Afrofuture Youth Detroit, which describes itself as Afrofuture Youth is a Detroit-based, black, youth-led organization using Black Futurist and healing-centered frameworks to co-create equitable and pleasurable futures where all aspects of black life can thrive and exist as they are.

The Afrofuture Youth Detroit is a non-profit organization that helps youth learn and practice organizing through learning and action. The participants were mostly in the age group 16-19 and were native to Detroit. The participants had diverse gender identities while being all native black Detroiters (a term they used to describe themselves). The author served as a facilitator and organizer of the workshop, and another faculty member observed for a partial duration.

3.2 Workshop Description

To expand on the workshop grounded in abolition principles and the critical jugaad framework, it's essential to focus on the transformative role of youth participants, particularly those from Afrofuture Youth Detroit, a grassroots organization dedicated to empowering black and queer youth through education and political awareness. This segment aims to detail the significance of their involvement, their unique challenges, and how the workshop serves as a pivotal platform for reimagining futures free from systemic oppression.

At the beginning of the workshop, we introduced ourselves in a very informal setting over lunch. During this time, the youth participants from Afrofuture Youth Detroit (AFYD) shared their experiences, interests, and ambitions. This allowed the design students and the youth to understand each other and get a glimpse of perspectives. Some youth shared their experiences of being queer and black in Detroit which was foundational in establishing trust in the communities. This was followed by an orientation presentation where we introduced speculative and critical design concepts, the need to establish a post-speculative and post-critical approach, and the methods of creating futures rooted in design education and practice. (See Figure 1) The students were foregrounded to the concept of critical jugaad and its role in our present and shared futures.

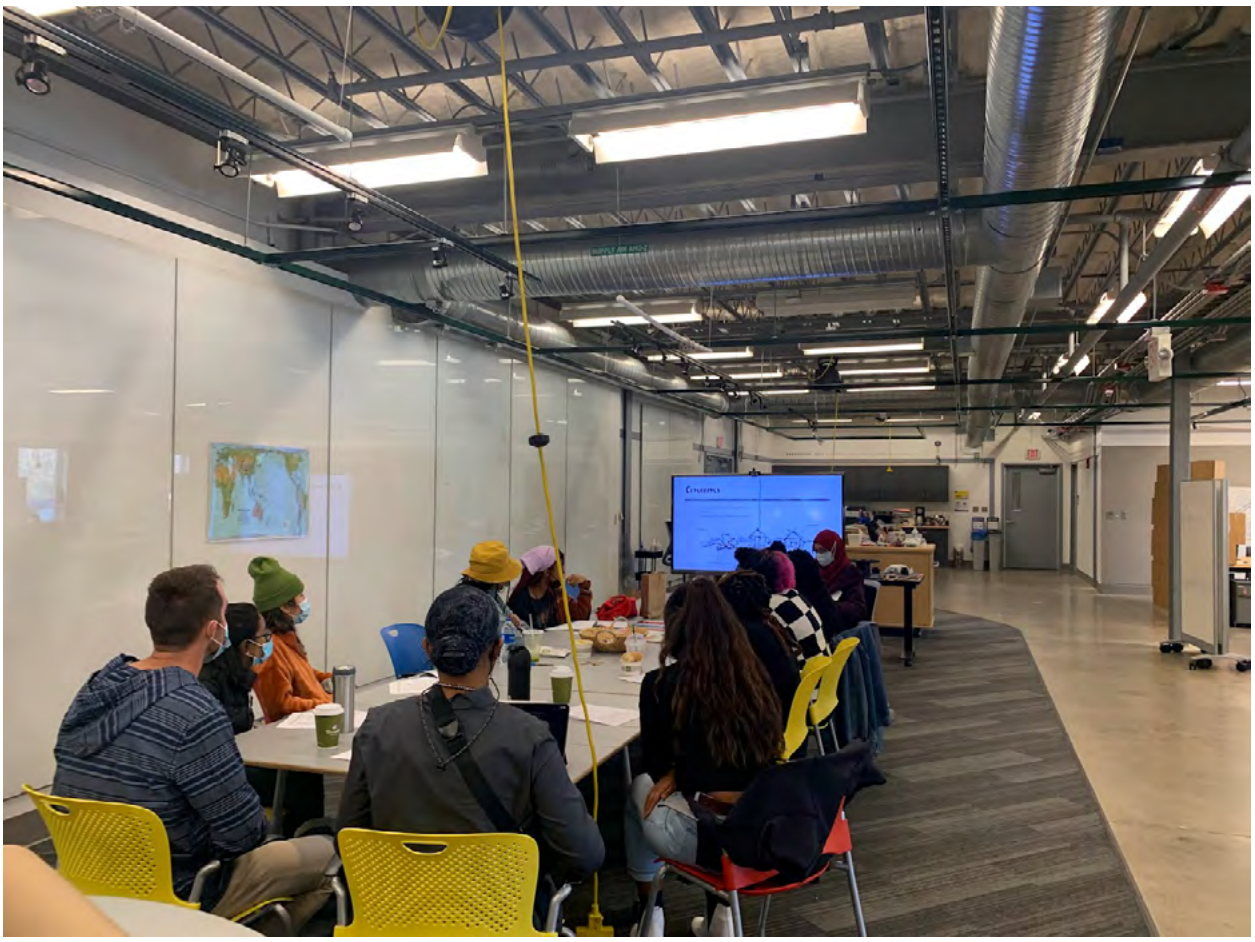

Figure 1. The workshop participants are oriented with the theories and concepts during a formal orientation session in a design studio at Stamps School of Art and Design, Ann Arbor, Michigan.

The tools used for the workshop were:

1. STEEP cards from IVTO.org;
2. Crit Kit toolkit (author, 2015).

STEEP cards are a set of foresight cards developed by IVTO- a research and education company in the Netherlands. STEEP is an acronym for social, technological, economic, environmental, and political. As mentioned on their website, STEEP is a structure used for scanning developments in the external macro environments. The STEEP set contains 134 cards, with 125 cards depicting external driving forces.

The other toolkit used here is the Critical Toolkit, developed by the author for critiquing critical and speculative design projects to make critique accessible to all and help individuals design their speculative and critical design projects. This toolkit consists of carefully considered question cards to self-evaluate the projects and a set of stickers with critical comments that could be posted on each other's projects during critique. (See Figure 2). The test cards playfully challenge participants on their bases and assumptions, making critical inquiry part of the imagination. The critical kit also contains a set of stickers that participants can use to critique each other's ideas. This playful activity helped participants ease the tension while reflecting on the challenges in their visions.

Figure 2. STEEP foresight cards, Critical Toolkit test cards, and stickers used during part one of the workshop.

The workshop was divided into two parts. The first part involved introductions amongst participants and facilitators and a description of theoretical frameworks followed by forming teams, with each team having youth participants and design students. The teams were then asked to choose one card from each category of the STEEP cards randomly. Using STEEP cards, the teams were asked to imagine scenarios for alternative futures for topics/situations like Urban Gardens or Public Schools, Energy infrastructure, etc. Youth participants and design student teams were prompted to visualize futures through discussions and imagination. They were given an option to draw or write their future imaginaries. Each team was asked to present to the whole group after 30 minutes of brainstorming.

In the second part of the workshop, participants were asked to use the critical toolkit to question those future visions to tease out the details and enable critical thinking using stickers or test cards. The next step was to return to the teams and reimagine what the future could be now with critical thinking and a mindset generated because of the critique of the future imaginaries created in the first part.

For the second phase of the workshop, the participant teams of both design students and the youth were asked to create their future scenarios or artifacts from the kludging of reusable materials procured from the scrap materials store and some from surrounding recycle bins. The teams were also provided basic assembly tools such as scissors, glue, x-acto blades, tape, etc. This workshop phase was met with much enthusiasm, and the teams were competing for unique objects to make their final prototypes/installations.

Materials for the workshop were obtained from a unique local store selling donated art and craft scraps, recycled materials, and items at a very low cost (see Figure 4). These materials would be usually discarded, but these items are sold in this store to find a renewed purpose and meaning. The materials obtained were unique and essential to the ethos of critical jugaad as we constructed visualizations for futures from found objects of our surroundings. Having an outlet where one could purchase things such as printer rolls, old

piano keys, bicycle handles, and much more served two purposes: One, it was an accessible resource for creating artifacts that didn't need much expertise and were non-intimidating to the youth who didn't have extensive art or design training. Secondly, such materiality simulated the realities of marginalized communities worldwide, where such items make the material for creative improvisation for survival and resilience (see Figure 5).

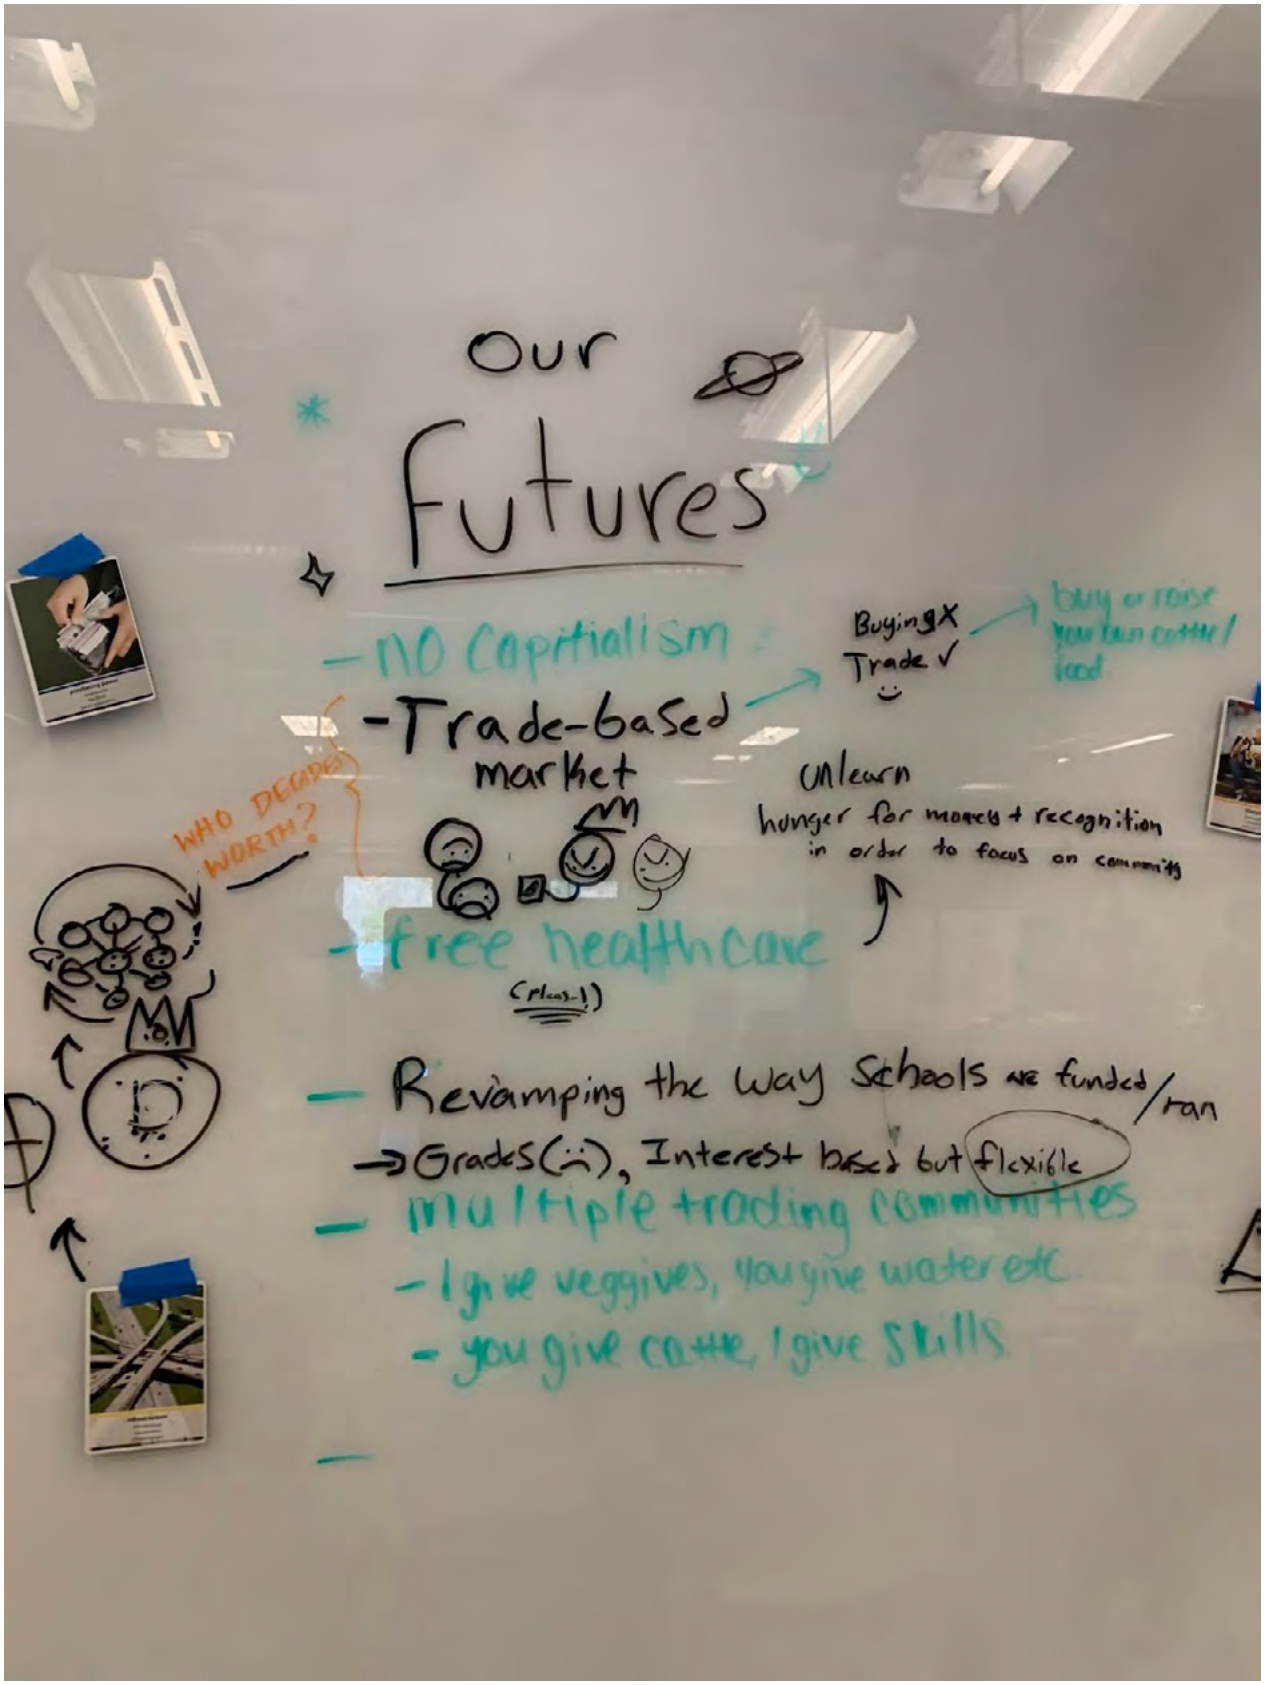

Figure 3. A whiteboard image of brainstorming done by one of the teams during the initial exploration sessions.

Figure 4. Scrap store in the Metro Detroit area where materials for the workshop were purchased.

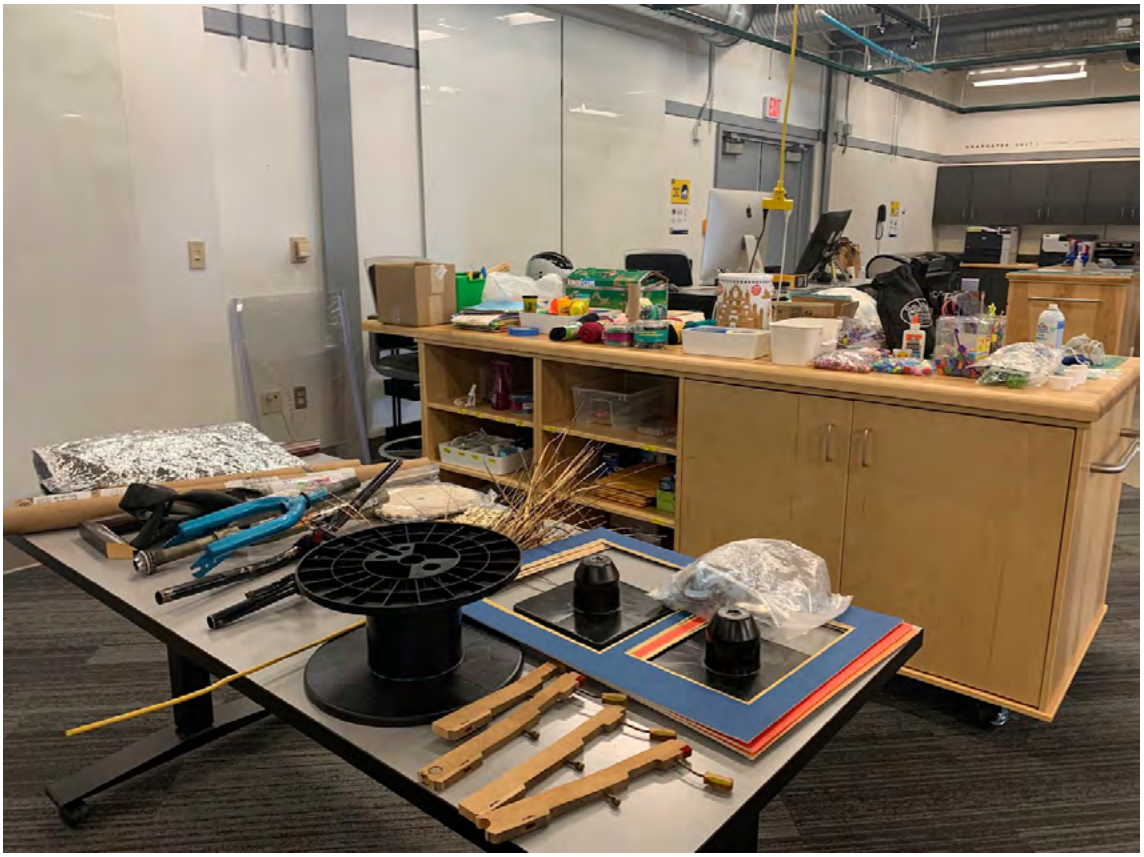

Figure 5. Materials provided to the participants during the part two of the workshop.

During the first phase, the teams developed a deep understanding of the topic from the perspective and lived experiences of black Detroiters. Some questions explored were: How can we imagine alternative energy methods? In the context of post-speculative& critical design and critical jugaad, this implied thinking about a local energy grid where water, electricity, and internet are mutually shared between the neighbors. However, after using the critical toolkit, the team later reflected that the existing power dynamics in Detroit would have to be navigated in doing so. The youth reflected on their experiences of water shutoffs and lack of infrastructure in neighborhoods with abandoned houses.

In thinking about the future with the intersection of critical jugaad and abolition, one team reflected on the importance of abolishing capitalism and establishing a trade-based market exchange. By “trade,” the participants referred to a barter system as an economic model. In the context of Detroit’s future, participants also expressed the desire to revamp the education system to create a flexible interest-based structure oriented to serve Detroit's black and marginalized communities (See Figure 3).

After understanding what critical jugaad signified in the context of abolitionist futures in Detroit, the youth participants were comfortable imagining futures where sharing and using what is available locally became central to futures thinking. Many ideas that had been visualized were practiced in Detroit at the time of this workshop, for example, urban gardens that shared food with neighbors and served as organizing places for connecting with others and seeking resources one might need at such community gathering places. Envisioning such currently marginalized practices as prominent Afrofuturist practices where belonging and care were placed as core values gave confidence to the youth as they expressed their future visions.

One of the youth participants mentioned, “I never knew I could imagine the future of my city and community using art and design.” Another participant felt that design practices could be emancipatory, and there was a lack of awareness in general regarding design as a practice in creating abolitionist Afrofuturist practices. They mentioned, “I did not know that (post-speculative) design methods could share common value with abolitionist principles.”

Figure 6. The final artifact created by one of the teams describes the future scenario.

In the making phase of the workshop, critical jugaad as a verb was instrumental in helping the participants create visions of Detroit's future. Critical jugaad advocates frugal decolonial methods for speculative and critical design practices for creating future imaginaries. One way to achieve that goal is to use materials deemed unworthy of purpose. The workshop, firmly grounded in abolition principles, introduced participants to the critical jugaad framework, where jugaad represents the art of resourceful problem-solving and creative improvisation. The amalgamation of these two paradigms allowed participants to reframe the dismantling of oppressive systems as an opportunity for constructing just and equitable alternatives—a notion at the core of critical jugaad thinking.

The participants navigated complex issues such as systemic racism and disparities in Detroit's black communities by making conversational artifacts from found objects. One of the youth participants conversed about the political conditions in Detroit using terms such as "tunnel of socialism and towers of capitalism," where the golden figure (as seen in Figure 6) represented capitalist power structures and socialist societies struggling to get to the top. While this was more about what they felt, another team created a model resilient future with urban gardens and food-sharing structures next to each other. This team also uses satire as a speculative tool to create a dystopian future scenario where shoppers at Walmart must shop in the fashion of "Squid Games,"- a popular Netflix show.

The "Making Just Futures for Detroit" workshop offered participants a transformative experience, blending critical jugaad with abolitionist design principles to reimagine urban futures. Participants, including local youth from Afrofuture Youth Detroit and MDES students, highlighted the workshop's capacity to break down traditional barriers in design, fostering a community-driven approach to addressing systemic issues. Through informal settings and participatory design sessions, they gained new insights into the potential of collaborative design, expanding their perspectives beyond conventional methodologies. Despite facing challenges in navigating the complexities of systemic change, the participants valued the workshop as a pivotal moment for personal growth and understanding the role of design in societal transformation. This reflection underscores the workshop's impact on individual participants and their collective vision for a more equitable and sustainable urban future in Detroit.

4. Discussion

4.1 The Significance of Engaging Marginalized Youth

Empowerment through Education and Political Awareness: Afrofuture Youth Detroit is crucial in educating young individuals on organization and political education. Integrating these youths into workshops that embrace abolition principles and critical jugaad thinking opens new avenues for them to understand the mechanics of oppressive systems and the importance of creative resistance. This approach educates and empowers them to envision and work towards just and equitable futures.

Addressing Unique Challenges: The youth participants, often marginalized due to their race, sexuality, or both, face systemic barriers that limit their opportunities for expression and innovation. Traditional educational and societal structures have failed to provide a supportive platform for their voices. Acknowledging these challenges, the workshop creates a space where their identities are affirmed, and their ideas are valued and nurtured.

4.2 The Workshop's Approach to Envisioning Futures

Reimagining through Critical Jugaad: The workshop introduces the concept of critical jugaad to navigate and dismantle oppressive systems through resourceful problem-solving and creative improvisation. This framework encourages participants to think outside conventional paradigms and use their unique perspectives to conceive solutions that reflect their desires for a just society.

Speculating on Future Possibilities: For many youths, the opportunity to speculate on the future in a structured and supportive environment is groundbreaking. The workshop validates their ideas and challenges them to expand their visions. By speculating on futures where equity and justice are central, they begin to see themselves as architects of change, capable of shaping their destinies and those of their communities.

4.3 Outcomes and Impact

- The workshop serves as a crucial outlet for these young individuals to explore and articulate their visions for the future by creating a safe space for exploration. It provides a rare, safe space where they can freely express themselves without the fear of invalidation or marginalization. This environment is vital for fostering a sense of belonging and confidence in their ability to effect change.
- Developing community-building solutions through collaborative discussions and activities encouraged participants to think collectively about their desired futures. This collective envisioning process not only strengthens community bonds but also leads to the development of innovative solutions rooted in marginalized communities' shared experiences and aspirations.
- Empowering Future Leaders by centering the workshop on the principles of abolition and critical jugaad, participants are equipped with the knowledge and tools necessary for leadership in their communities. They emerge as empowered individuals ready to challenge oppressive systems and advocate for equitable alternatives.
- Developing methodologies for post speculative design and training design students in community engagement.
- In the long term, design students were thoroughly impacted by the energy and stories of the participants and their capacity to hope for a positive future for all despite facing racism and oppression for most of their lives. In the short term, this workshop influenced their work in their efforts to imagine just futures for marginalized communities in Detroit.

5. Conclusion

The inclusion of youth from Afrofuture Youth Detroit in workshops centered on abolition principles and critical jugaad thinking is more than an educational endeavor; it's a transformative experience that validates their identities, amplifies their voices, and equips them with the tools to reimagine and build futures where justice and equity prevail. This initiative fosters individual growth and cultivates a generation of leaders committed to dismantling oppressive systems and creating inclusive, equitable communities.

Combining abolition principles with the critical jugaad paradigm presents a transformative potential beyond traditional urban development and social justice approaches. By intertwining the principles of abolition, which aim to dismantle oppressive systems, with the creative and resourceful problem-solving approach of critical jugaad, this methodology offers a unique pathway for reimagining and reconstructing urban spaces. It encourages the empowerment of marginalized communities, ensuring their voices and needs are central to developing equitable and sustainable futures. This approach challenges existing power dynamics and fosters resilience and innovation from the ground up, providing a robust framework for addressing complex urban issues.

The implications of this combined paradigm are vast, suggesting a shift towards more inclusive, participatory forms of urban planning and community development. It emphasizes the importance of grassroots involvement and the value of local knowledge in creating solutions that are genuinely responsive to residents' needs. As cities continue to evolve, integrating these principles can lead to more just and vibrant urban environments that reflect the diversity and aspirations of their communities.

Future research should explore the application of these paradigms across different urban contexts, examining the outcomes of such approaches in various settings. Studies could focus on how these principles can be effectively integrated into urban policy and planning, identifying best practices for fostering community engagement and empowerment. Additionally, research could investigate the scalability of projects developed under this framework, assessing their potential for broader impact on urban transformation and social justice.

Although there were no direct implications regarding projects from this workshop immediately after the workshop, the participants continued working on their individual projects with renewed perspectives. The author and the founder of the AFYD worked to develop a new version of the Afrofuture Youth Festival in Detroit and an exhibition for futures from Detroit, which is not within the scope of this article to discuss.

KEYWORDS | DESIGN-ORIENTING SCENARIOS, ALTERNATIVE FOOD NETWORKS, URBAN FOOD SYSTEM, REGENERATION

ABSTRACT | Environmental crises, social and economic challenges, and technological uncertainties highlight the urgent need for more sustainable food systems. While food affects climate change and inequality, these issues also influence food security. In this context, Alternative Food Networks (AFNs) offer promising ways to renew our relationship with food from production to consumption. This paper offers a speculative and design-led perspective on emerging practices within AFNs, proposing scenarios for Milan's food system in 2035. Two main uncertainties create these scenarios: Governance, which looks at power and decision-making dynamics, and Approaches, which examine how institutions and societies respond to environmental and social issues, emphasising either adaptation or mitigation strategies. Using the design-orienting scenario theory, we outline four possible futures in 2035, considering innovations at the actor level, their relationships with actors at the system level, and broader societal changes. This paper concludes by proposing the concept of "regeneration" as essential for shaping future food scenarios. "Regeneration" refers to the process of reclaiming, maintaining, and restoring the health of ecosystems to enhance resilience. This approach goes beyond ecological health to foster positive outcomes for and with urban ecosystems, suggesting the renewal of societal relationships and structures. It emphasises the crucial role of engaging diverse actors—AFNs, citizens, and mainstream stakeholders—in different ways to create food futures that are not only environmentally sustainable but also socially equitable.

1. Background: Food System Challenges and the Promise of Alternative Food Networks

As we face an environmental crisis, growing social and economic vulnerabilities, and technological uncertainty, it becomes clear that we need to move to more sustainable and resilient food systems (Serraj & Pingali, 2018). From production to consumption, food significantly impacts climate change and social inequality. At the same time, climate change disrupts food security, water security, and agricultural productivity, making it difficult to achieve Sustainable Development Goals (IPCC, 2023). In other words, food affects climate change and inequality, while these issues also put our food supply at risk.

The COVID-19 pandemic and the conflict in Ukraine have made it more evident that the current food system cannot provide food access to all (FAO, 2023). This has increased interest in alternative food networks (AFNs) as a potential solution, as more research focuses on how AFNs and shorter supply chains can drive sustainable change on a small, local, and connected scale (Gori & Castellini, 2023).

AFNs introduce different ways of producing, distributing, buying, and consuming food (Barbera & Dagnes, 2016). Since they work to minimise environmental and social damage, they adopt cleaner and fairer practices, which have a positive impact on the sustainability of the entire supply chain (Bush et al., 2015). A look at Milan, Italy, illustrates how AFNs create new supply chains and leverage the infrastructure of conventional ones (Food Policy di Milano, 2021). After the 2015 Expo 'Feeding the Planet, Energy for Life,' AFNs in the city began using the resources of traditional players to create new solutions for food access. This practical approach shows how AFNs can collaborate with the mainstream food system to develop alternatives.

In this context, we recognize the opportunity for systemic rethinking within Milan. The city, already transforming its food practices since the 2015 Expo, has developed multiple initiatives aimed at varied aspects of the Milanese food system. Although the AFNs in urban and peri-urban Milan have shown promise in creating more sustainable and equitable food practices, the broader context calls for a deeper transformation. How can we extend the impact of these networks? To this end, this paper presents an in-progress work of envisioning scenarios for peri-urban and urban areas of Milan to introduce a speculative perspective on existing trajectories of development driven by design.

These scenarios act as an envisioning tool, an "interaction platform," and a springboard for generating "design-driven conversations" with different food system actors through co-design workshops. They will help identify contexts that improve food access in the city and become a catalyst for creating pre-prototyping and design activism actions, highlighting potential evolutions of the Milanese food system. This research is a part of the ongoing project named OnFoods, a research programme dedicated to the Sustainable Development of Food and Nutrition, supported by funding from the National Recovery and Resilience Plan (PNRR). More specifically, this paper focuses on a series of research activities and design actions conducted by the Polimi Desis Lab of Politecnico di Milano within the OnFood project and focused on enhancing the efficiency of food value chains to ensure food access for the most vulnerable sections of society.

Following this introduction, the paper presents current trends and emerging practices in the agri-food industry in Europe. Section 3 then outlines the methodology for scenario building. Section 4 presents four scenarios for the Milanese Food System and their application in three co-design workshops with food system stakeholders. Section 5 reflects on the workshops' outcomes and suggests that the current scenario-building strategies, which focus on adapting to and reducing negative impacts, should shift towards the concept of regeneration. This approach considers both social and ecological aspects to envision food futures that are not only carbon-neutral but also socially equitable.

2. Design-Orienting Scenarios

Scenarios facilitate open conversations around visions and solutions between the actors shaping the food system. Exploring scenarios encourages actors to share their different positions, concerns, and future goals, activating new discussions and even shared visions (Manzini & Jégou, 2004). The importance of participatory approaches lies in the fact they can help create visions with a plurality of perspectives and a better understanding of preferences (Heidingsfelder et al., 2015).

The goal of the research project is to use these scenarios as triggers to develop pre-prototypes. In this context, pre-prototypes become design activism actions meant to showcase new Alternative Food Networks (AFNs) and cross-sector partnerships in the city, involving different levels of society and opening the discussion for policymakers and local actors. Working with scenarios also presents an opportunity to invite actors from the food system to sit at the same table and share provocations that could eventually spark changes at the food policy level. Given that scenarios will provoke participatory ideation, the method used during this first phase was the one of design-oriented scenarios (Manzini & Jegou, 2000).

Unlike policy-oriented scenarios (POS), design-oriented scenarios (DOS) are "design-oriented" because they are motivated, illustrated, and visualised with specific solutions, representing a range of perspectives to be discussed. They address specific actors, showing how their decisions affect a focused system to help them orient their future (Manzini & Jégou, 2000). DOS can have different goals depending on the project's focus and the moment of the process in which they are used. Teams can apply them in a phase of exploration or focalization focusing on actors or results. Setting these conditions allows teams to define if scenarios help explore opportunities and possibilities or individuate a product system or solution (Manzini & Jégou, 2004). Through the DOS framework, teams can also determine the motivation and practicality of their scenarios, understanding their aim and the steps to facilitate their implementation (UNEP, 2009). Scenarios are here geared towards exploration and results. They are Function-based DOS since they focus on the food system, sharing macro and emerging trends and how several actors and their behaviours could affect the evolution of the entire system and the actors themselves (Manzini & Jégou, 2000).

The actors within the designed scenarios address are the food system nodes. A 'node' is a pivotal point (digital, physical, or both) where significant activities and interactions related to food production, transformation, distribution, and consumption occur (Aucoin & Fry, 2015). The nodes in the scenarios presented in this paper are part of AFNs: actors that interact and share resources and infrastructure with AFNs, and actors that could play a role in developing and supporting current or new AFNs. As an example, in the Milanese context, these main nodes are the wholesale market, indoor and outdoor markets, the farmers' markets, the food waste hubs[1], and public canteens. Although characteristic of Milan, these nodes constitute an interconnected network in other European urban areas.

3. Developing Scenarios for the Milanese Food System of 2035

The scenario-building process comprised three main phases, each with different steps. The first phase involved case study research and analysis to identify promising practices and food system nodes to engage, including desk and field research, interviews, and internal problem-framing workshops. The second phase focused on research around trends, drivers, and policies related to the challenges and critical topics recognized in the previous phase and about urban and food matters in general. The scenario-building phase developed future visions using the 2x2 matrix technique and the design-oriented scenarios approach. Finally, a workshop tested the scenarios with researchers from OnFoods and from the departments of Politecnico di Milano.

[1] Milan food waste hubs have "the aim of reducing food waste and innovating the ways of recovering food for the people in need, designing and experimenting a model of collection and redistribution of food surplus, based on local neighborhood networks" (Milano Food Policy, n.d.).

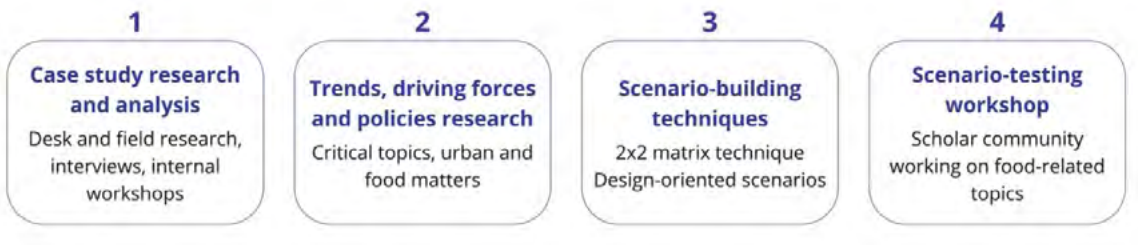

Figure 1. The scenario-building process.

3.1 Research Baseline

The process for creating scenarios began with case study research and analysis to create a detailed image of the Milanese Food System, its nodes and actors, and how these interconnect. This initial research helped identify active, inactive, and new nodes, their purposes, and barriers, which ones are enabling and part of AFNs, and which ones play or could play a role in supporting current and prospective AFNs. Interviews helped better define activities and barriers and understand their vision for the future. Finally, a workshop within the Polimi Desis Lab transformed barriers and opportunities into challenges to tackle, which the authors clustered into seven topics future visions should address: diet and sustainability, good and fair food, collaborations as integration of services, service model logistics, optimization, escalation and replication, and urban production.

3.2 Driving Forces, Trends, and Promising Practices

After identifying the nodes for scenario building, the team looked at the macro, emerging, and niche trends, driving forces, and policies at the local, national, and regional levels. This research allowed a deeper understanding of the seven topics and how Milan's food system might evolve. The aim was to identify emerging values and behaviours in AFNs and other players and detect signs of change at the micro, meso, and macro levels to understand how particular trends would react over time in determining the future of food in the city. This exploration considered food-related and food-influencing factors such as urbanisation, mobility, housing, migration, and health, including themes like the city's push towards sustainability, the growth of the elderly population, the immigration of the young population into cities, the increase of technology and digitalisation in all areas of life, European and Milanese mobility regulations for 2023, urban lifestyles, the customers' awareness of climate change, and their changes in health habits and routines.

As a result, the authors identified examples of food practices relevant to more sustainable and fair food systems in European AFNs, e.g.:

- A shift towards avoiding waste and reducing consumption (e.g., food rescue, purchasing "enough," locally sourced food) shows opportunities for more efficient food consumption.
- A shift towards self-sufficiency and including diners in transforming their food (e.g., urban farming; student-run canteens) shows how people move from food consumers to food co-producers.
- A shift from food ownership to food access (e.g., sharing, swapping) shows a different way to consume.

The authors integrated and projected these more virtuous practices to create four desirable scenarios for a fair and sustainable food system in Milan in 2035. Working within a 10-year timeframe allows for open discussions between food system actors that invite new and forward ideas while remaining grounded in what is feasible, viable, and possible today. Later in the research process, these conversations will serve to understand the priority issues for each actor and as the base to kick-start pre-prototyping actions that showcase the food system's evolution and new partnerships.

3.3 Polarity Mapping and Design-Orienting Scenarios

As anticipated, the project employed a specific scenario methodology - design-orienting scenarios (DOS)- to create visions for the Milan food system and specific nodes. We can identify these scenarios as preferable futures (Dune & Raby, 2013), concerned with practices that we, as designers, believe are promising and desirable for the nodes from business, social, and environmental points of view.

The scenario-building phase used the 2x2-matrix technique, crossing two critical uncertainties (highly impactful issues for the future of food) with opposing polarities to generate diverse future scenarios (Rydderch, 2017). Given the focus on DOS, meant to provoke specific actors, ten years was a time frame that allowed us to mix high-impact uncertainties with feasible technologies and consumer behaviours. The team based the selection of critical uncertainties on the idea that the scenarios should:

- Reflect on the topics and promising practices uncovered by the first two research phases,
- Differ from policy-oriented (POS) scenarios, allowing for actor-specific narratives,
- Reflect issues critical in existing research on sustainable food systems and production/consumption patterns.

The first uncertainty is about governance structures, focusing on the distribution of power, decision-making processes, and compliance. This leads to two polarities: Centralised governance, where decision-making is concentrated in a few hands, and Distributed governance, which spreads power across a wider network of participants. The second uncertainty examines the approaches to addressing environmental and social issues, questioning the innovation strategies employed by society and institutions. The polarities here are Adaptation strategies, which battle the effects of phenomena, and Mitigation strategies, aimed at tackling the root causes of phenomena.

Climate change research identifies mitigation options as those strategies that prevent or reduce the emission of greenhouse gases, which cause climate change. Avoiding or reducing emissions requires society to change everything we do—from our lifestyles to how we produce our food, energy, and products—for example, changing to plant-based diets or reducing consumption. On the other hand, adaptation focuses on tackling the effects of climate change and modifying how actors operate to become more resilient. These strategies work on adapting to the climate changes that are already happening or are soon to happen—for example, heat and drought-resilient crops (Wang et al.,2023).

Given that AFNs tend to pursue environmental and social aims, the impact of the climate crisis on the urban population, and the role of social behaviours in shaping future strategies, the social dimension was necessary for strategies in these scenarios. Following the same logic of adaptation and mitigation used in climate change strategies—addressing effects and causes—we also applied these concepts to social phenomena. For instance, when considering unemployment rates among migrant populations, an adaptation strategy might involve enrolling them in a food stamp or donation program to ensure they can access food. On the other hand, a mitigation strategy would address the root cause by including individuals in job insertion programs and integrating them into the workforce.

Mitigation and adaptation strategies are promising for improving environmental and social resilience, and feasible, effective, and low-cost options exist. We can bring significant environmental and well-being benefits by integrating these strategies into social programs, such as promoting consumption reduction practices or lifestyle changes (IPCC, 2023). Design can be crucial in this area, especially in the food system. Design has shaped food systems for a long time, starting from product, communication, and packaging, and moving to services, systems, and strategies. The food value chain offers several design opportunities for problem finding, framing, and solving, which can support the city's adaptation and mitigation strategies.

The combination of the two critical uncertainties created four possible future visions, each with specific features of governance and strategies (Figure 2).

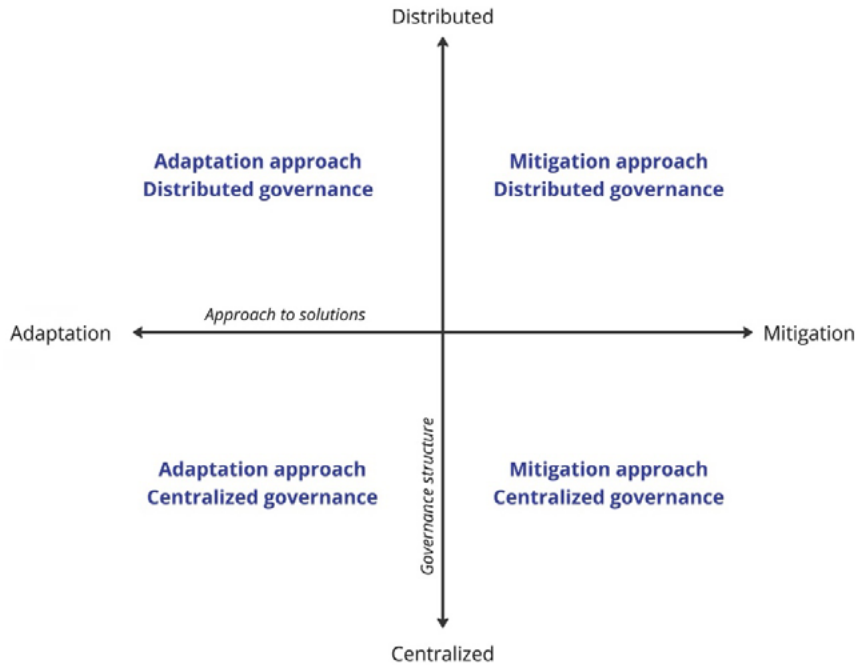

Figure 2. The 2x2 matrix and the resulting critical uncertainties.

3.4 Scenario Components

The drivers and trends coming from previous research informed the storytelling, creating a believable context to place our provocations, or story layer (Lindley & Coulton, 2014). Each scenario consists of five main elements. The story includes a name, a brief description, and a longer one that details three levels: micro (actor), meso (system) and macro (city and beyond). 'Sustainable qualities' (Manzini & Tassinari, 2012) — key elements from Alternative Food Networks (AFNs) that we aim to promote in services and interactions —support the story. Finally, technology serves as an enabler for innovation.

The scenarios take shape through the story layers. The first one, the Macro level, defines the overall context holding the food system together. It describes the macro changes in urban areas and frames the food system in an urban, regional, and national setting. Trends, policies, and driving forces were the main stimuli for creating this first layer. The Meso level focuses on the vision of the food system, and it works as a first provocation layer for the actors. It considers the future of nodes and actors' relationships and how power dynamics work around them. Therefore, governance highly influences this layer. Finally, the Micro level focuses on the vision for specific food system players and works as a second provocation layer. It describes the node-level strategies, practices, solutions, and features that could facilitate changes in that context. Consequently, the approach to strategies primarily influenced this layer.

In addition to the critical uncertainties and their polarities, other key ingredients influence and shape each scenario. These are the sustainable qualities and enablers, common elements that hold different weights depending on the scenario. Manzini and Tassinari (2012) define sustainable qualities as "features that are better than the ones proposed by the mainstream unsustainable production and consumption system" (p.08). Using this definition, we adapted these qualities for our scenarios, influenced by their reflection on Alternative Food Networks (AFNs). The result is four qualities and one enabler, detailed in Table 1 below. Together, the different weights of sustainable qualities and enabler(s) add an extra layer of information to build each scenario's identity.

Table 1. Sustainable qualities and enablers adapted for this project.

Sustainable quality	**Definition**
Integration	How integrated are services between each other?
Collaboration	Does the innovation promote collaboration among different actors? Does it promote cross-sector partnerships? Does it include final users in the design and delivery of the service?
Engagement	Does the innovation require a high degree of engagement or self-organisation from actors?
Building capacities	How much does the innovation build competence and capacity across society?
Enabler	**Definition**
Technology	How much is technology integrated into the solutions?

In our four scenarios, we see technology as an enabler of change, recognizing its potential to reshape food systems dramatically. In the Data-Driven Renewal scenario, we feature AI as the primary technological advancement to understand the readiness of various actors within the food system to adopt and engage with new technologies and to begin dialogues about their use. However, we're also aware of the broader impact of these technologies, from the energy they consume to the materials they require and the social repercussions they might carry, particularly concerning data use and materials sourcing.

4. Results

The resulting four scenarios are short narratives describing how actors—the food system nodes and their stakeholders—might behave and interact in 2035 Milan (Figure 3).

Food Communities

Food Communities shows a future in which food ceases to be an individual issue and becomes a communal one. Citizens and residents have adopted a shared approach to food and have taken to participate in the changes in the food system nodes. The municipality has taken a proactive step in facilitating this trend by providing regular meeting spaces for various stakeholders in the food system.

While neighbours now meet, co-create, and develop strategies to transform waste, schools teach children how to transform food surplus. Food swap, donation, and distribution are organised by each neighbourhood, with open communication between all. The city is repurposing buildings and revitalising neighbourhoods, and citizens are proud to learn new skills to make the most of what they have.

Farmers share strategies - such as crop rotation, crop adaptation, and water usage optimization - to adapt to the changing climate in the region while those most affected by droughts and floods receive financial support from the government.

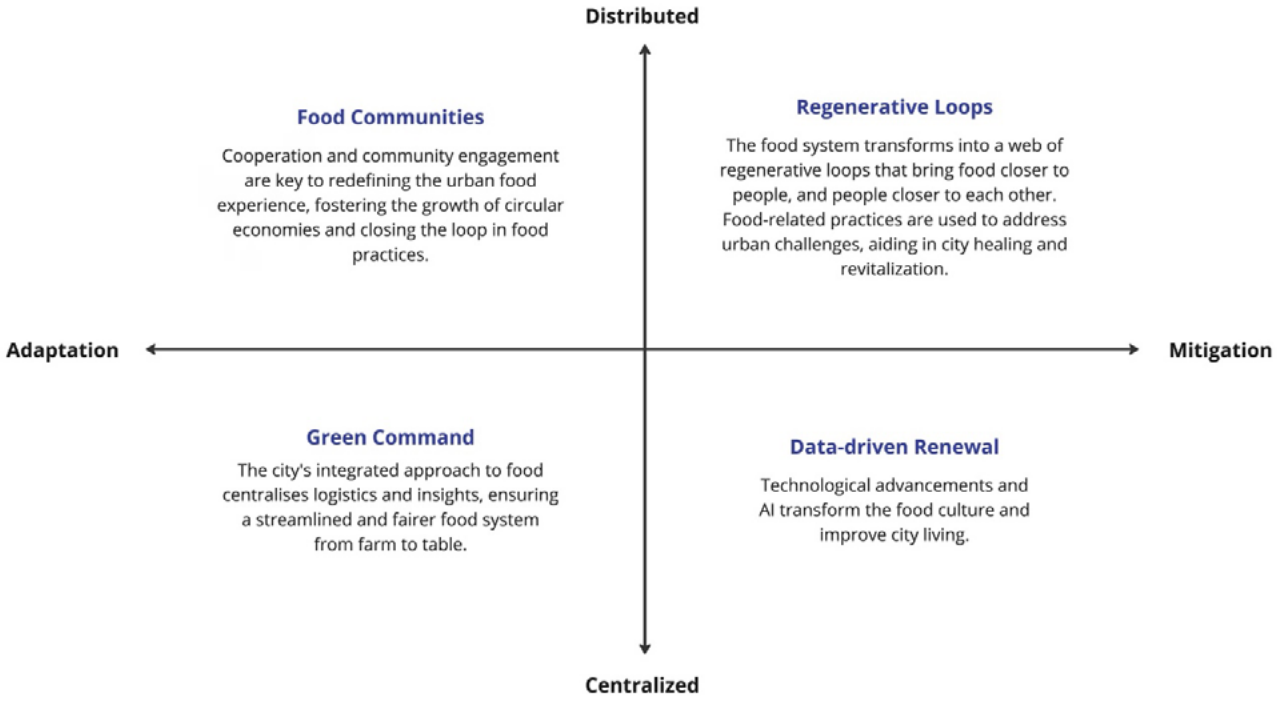

Figure 3. The resulting scenarios and their short descriptions.

Green Command

In Green Command, the municipality collects and integrates information about the food flows and food needs across the city to gain valuable insights. At the same time, they implement strong regulations regarding food production, distribution, and consumption as well as set standards for transportation and storage. These normative initiatives help in establishing markets and food hubs strategically and ensure changes from local producers and food system actors. This effort simplifies the process of donating surplus food and centralises logistics, making the system fairer and more effective.

There is a solid push to invest more in locally grown produce and to provide support programs, including skills training and subsidies, for farmers, especially those in peri-urban areas, enabling them to become more prominent players. New technologies around food are becoming widespread and accepted by the public as laboratory meat enters the market, dehydrated food, and similar technologies to prolong food life become widespread and government funds are dedicated to researching crops that are heat and drought resistant.

Citizens receive constant reports about the food they eat and are notified about existing more sustainable and healthy food alternatives. Motivation and awareness are rewarded and drive changes in everyday consumption.

Regenerative Loops

Regenerative Loops envisions a future in which the city's food system is more capillary, with urban and peri-urban farming flourishing. Parco Agricolo Sud Milano sets a precedent in regenerative agriculture and resilience against climate change, showcasing permaculture and agroforestry practices. Food production happens within and around the city, with an emphasis on high-quality food, accessible to all in the present and for future generations. While farmers gain more access to public incentives when they join cooperatives and networks, public institutions receive incentives to buy from urban and peri-urban farming.

These changes are supported by local policies that foster collaborations and strengthen emerging small-scale initiatives, encouraging the formation of localised food loops across neighbourhoods. Green areas are taking the space of cars and neighbourhoods have access to spaces for food production or transformation,

such as the neighbourhood food hubs, supporting the city's growing focus on self-sufficiency. These changes have generated new jobs in this field, and since everything develops in small areas, people can easily access all the services they need within a 15-minute radius.

People's perception of food transforms, embracing 'ugly' but delicious produce, leading to policies that reduce aesthetic standards for fresh food and promote hands-on school food lessons, helping youth learn practical skills. Household food waste significantly drops as residents adopt more responsible purchasing and consumption habits. They use apps to monitor expiration dates and to cook with whatever is at hand. Local policies encourage networks and technologies to minimise home food waste, to advocate for plant-based diets, to use unpackaged products, and to promote returning distribution packaging to suppliers.

Data-Driven Renewal

In this future, the municipality aims for high-quality food for all in present and future generations, through the support of technology.

The municipality uses AI and real-time data to predict challenges, react immediately by adjusting micro-policies and actions, and improve their impact. This focus on data, AI, and blockchain helps to optimise the system, minimise waste, increase the efficiency and transparency of the food system, and allow for continuous prototyping of incremental innovative solutions.

As the local government raises awareness and implements policies to support vegetarian and vegan diets to lower carbon emissions, people's shopping and eating habits gradually shift by having access to personalised and optimised menu options. Supermarkets, local markets, and canteens use this technology to offer a variety of fresh produce and vegan options, ensuring access to high-quality, affordable food all over the city.

Energy policies have transitioned from fossil fuels to renewable sources, encouraging food industry players to adopt renewables in transportation and logistics and to decrease transportation distances and displacements by optimising them.

Table 2. Summary of scenarios and their defining characteristics.

Scenario name	Food communities	Regenerative loops	Green command	Data-driven renewal
Quadrant	Adaptation approach + Distributed governance	Mitigation approach + Distributed governance	Adaptation approach + Centralised governance	Mitigation approach + Centralised governance
Short description	Cooperation and community engagement are key for redefining the urban food experience, fostering the growth of circular economies, and closing the loop in food practices.	The food system transforms into a web of regenerative loops that bring food closer to people, and people closer to each other. Food-related practices are used to address urban challenges, aiding in city healing and revitalization.	The city's integrated approach to food centralises logistics and insights, ensuring a streamlined and fairer food system from farm to table.	Technological advancements and AI transform the food culture and improve city living.
Scenario keywords	bottom-up initiatives, neighbourhood scale, engaged citizens, low technology, sharing	production, care, capillary and connected, specialization, future generations, 15-minute city	technocratic, normative, monitoring and tracking, optimization	high-tech, predictions, anticipation, rapid response

Collaboration	Medium	High	Low	High
Engagement	High	High	Low	Medium
Technology	Low	Low	High	High
Relevant nodes	Farmers market, Food hubs, Covered markets	Farmers market, Covered markets, Food hubs	Wholesale market, Farmers	Wholesale market, Farmers, Food hubs

4.1 The Co-Design Workshops

The project aims to use participatory approaches in specific contexts of experimentation to improve fairness, efficiency, and awareness around food systems. Here, scenario building is crucial. Therefore, three workshops tested the scenarios to initiate conversations around the key projects and actors that influence these future visions.

The first workshop involved researchers from different areas, including management engineering, architecture engineering, and design, currently working on OnFoods in Politecnico di Milano and on food-related topics. After an initial presentation of the four scenarios with the proposed visions of the Milanese Food System nodes, participants worked in groups around the nodes they felt more knowledgeable about. The nodes participants worked with were the wholesale market, covered markets, street markets, food redistribution hubs, farmers' markets, and canteens. Each group imagined how their node would change in each scenario, which node-related activities were the key for each context, and their node's relationship with other players in the system—a moment of reflection on the current situation followed this exercise. Then, participants identified existing projects or actors working on similar practices to the ones the scenarios presented or with enough influence to impact them. The workshop concluded with a shared space where the participants and facilitators shared and built upon each other's ideas, some of which were collaborations the scenarios did not consider.

This initial workshop was an opportunity to validate the scenarios and their use in a co-design session with an academic community. It also provided new knowledge about the Milanese food context and existing

projects working towards these future scenarios. This session's list of actors and projects helped define which stakeholders to involve in the second and third workshops.

The second workshop focused on the wholesale market, bringing together its market director, the institutional and external relations manager, and the project and property manager. This workshop explored potential developments in the wholesale market's main role—for instance, as an enabler of urban production or a facilitator of food logistics in the city. These roles translated into specific services that would link the market with various nodes throughout the city. The session aimed to pinpoint areas of interest and determine their priority.

The third workshop involved actors from the Milanese food redistribution hubs (the Milan Food Waste Hubs). By March 2024, the city had five hubs donating food to citizens in conditions of vulnerability, with three more planned. The workshop involved nine people working directly in the hubs or third-sector organizations connected to them. The hub system has several tasks: food collection, distribution, assembly, and delivery. The actors attending the session were involved in one or more of these tasks. The session followed the same agenda as the previous workshop. First, participants learned about the four scenarios and the evolution of the hub's role in them. Then, the facilitators presented six service ideas related to those scenarios, and finally, there was time to debate about those ideas. As a result, the session shed light on the importance of implementing optimised logistics systems and communication channels, as well as learning spaces for beneficiaries of the service. On the other hand, it highlighted the need to involve the public administration in the conversation to open the debate around food policy updates and regulations.

Further workshops will involve stakeholders representing the covered and street markets, public canteens, and the consumers and beneficiaries of the services impacted by the four scenarios. The final goal is to envision the priority work areas for each node and the food system, their drivers, barriers, and possibilities for collaboration. Having these issues apparent will help the team develop pre-prototypes of new possible services and collaborations in 2035 that the system could work towards today.

Figure 4. Workshop context, participants, and materials.

5. Discussion

The interconnection between food, climate change, and social inequalities highlights the need to redesign our food system. In this context, Alternative Food Networks (AFNs) suggest new directions for making food systems more sustainable and fairer. They highlight how food system actors and consumers are increasingly aware of the social and environmental issues within the food system and how ready and capable they are to create alternative solutions based on a different paradigm. They also reveal opportunities to renew governance structures for tackling food-related challenges.

This paper adds to the ongoing discussion around food system transformation by introducing a speculative, design-led approach. Drawing from current trends and alternative development paths, design-orienting scenarios (DOS) explore future visions for Milan. The four scenarios share ideas around food that seem more virtuous and promising, showcasing futures where increased well-being is not linked to increased consumption or more intensive use of resources. They also centre around the transparency of information and the active participation of mainstream and alternative food system actors as well as consumers—characteristics AFNs showcase. These are scenarios that aim to activate discussions between food system actors, visualising alternative solutions and collaborations that simultaneously produce environmental and social gains. Not one before the other, but ideally hand in hand.

Carefully looking into the three co-design workshops revealed that the governance axis of the scenarios provided an opportunity to address social interactions as the roots of change (through changes in behaviour, power dynamics, and decision-making processes). However, the approaches axis, which focused on how institutions and society address environmental challenges, fell short to represent the social aims AFNs also have besides the environmental ones. During the discussions based on the four scenarios, the participants aimed to develop ideas that not only focused on environmental care but also embraced a more comprehensive approach to consider social and ecological aspects together. Here is where the real challenge for envisioning more fair and sustainable food systems emerges: integrating these aspects and using them as the background to envision new and more sustainable solutions.

The adaptation and mitigation concepts can be further advanced into the future by considering the concept of “regeneration” as a transformative opportunity not only of practices but also of relationships. Building on the definition provided by the EMF (2015), regeneration involves the process of reclaiming, retaining, and restoring ecosystem health while improving resilience. We aim at expanding this concept as critical in shaping food scenarios, to include the development of positive outcomes with and for the urban ecosystem. This implies revitalising the system of relationships and society at large. This transformation must involve all actors—AFNs, citizens, and mainstream stakeholders—highlighting how to activate people and players in different ways and allowing us to envision food futures that are not only carbon-neutral but also more socially equitable. The concept of regeneration is based on adaptation and mitigation strategies, but it wants to go further and include an aspect of visioning an inclusive, generative, and proactive future, where a predictive approach is in fact linked to a capacity to react to unforeseen aspects. The capacity of actors to act, their agency capacity, is embodied in a collaborative approach that frequently materialises through cross-sector partnerships. This dynamic becomes a crucial element in effectively navigating the intricate contexts of relationships and interdependencies.

Even though the challenges and actors presented in this paper are characteristic of the Milanese context, the insights from the workshops carry general relevance, suggesting ways that similar cities might approach food system sustainability. The situation in Milan reveals the importance of continuously aligning city food policies with on-the-ground realities. The current mismatch between practice and regulation in the city results in food waste, inequalities in access to food, and complicated procedures for those trying to improve food security.

Workshop participants recognized the need for a coordinated effort that aligns different actors and their strategies. While individual efforts have an impact, a collaborative infrastructure can lead to more strategic

and responsive solutions. A systemic approach—one that addresses the entire food chain—is crucial for interventions to be resilient and long-lasting. The critical role of connectivity between different food system nodes, such as the dialogue between covered and wholesale markets or between food hubs, underscores this need.

The four future scenarios and the three workshops implementing them have set the stage to help us envision, alongside Milanese food system actors, new AFNs in the city and rethink different city nodes regarding food. This effort aligns with the Milano Food Policy, the municipality's strategic plan governing the urban food system since 2015 to make it more sustainable from all perspectives.

KEYWORDS | CRITICAL DESIGN; SUSTAINABILITY; GRAPHIC DESIGN; T-SHIRT DESIGN, AESTHETIC RESISTANCE

ABSTRACT | Oppose 1984 in 2030: Keeping the UN Goals on an ethical path' (short: Oppose1984in2030) is a Critical Design project currently being developed by the author at The Royal Danish Academy – Architecture, Design, Conservation. This experimental academic practice-based research project involves communication design (graphic design on t-shirt artifacts) combined with ongoing critical meta-research in the political economy of sustainability issues.

The project aligns itself with the approach of critical design in questioning conventional design norms. However, it diverges from the typical speculative design by not aiming to create designs based on favored visions. Instead, it takes a contrasting stance, serving as a precautionary measure by designing against undesirable (totalitarian) future scenarios.

While oppose1984in2030 is grounded in the critical design discipline, its purpose extends beyond merely challenging established modes of thinking and behavior; it serves a more idealistic and impactful role: The emphasis is entirely on being critical to confront the totalitarian blueprints being pursued by an expansive oligarchic global system of monopoly capitalism who uses sustainability discourse to lead humanity towards '1984 in 2030'; a phrase inspired by the title of George Orwell's renowned novel but combined with the UN's sustainability visions of Agenda 2030.

Like typical critical design, the design activism of this project is not driven by commercial considerations. However, the design prototypes of oppose1984in2030 are not industrial design as in the work of Dunne & Raby (2001, 2013). Instead, the territory is communication design; the t-shirt artefacts with typography signify something about sustainability and totalitarian issues that are exterior to the actual prototypes. The prototypes can be reproduced in several copies to let the design engage in everyday life through t-shirt-wearing subjects. The subject's experience can then later be introduced into an exhibition space through visuals and written information. The concept of 'Aesthetic Resistance,' as formulated by John Steppling (2020), serves as a distinct source of inspiration. Stepping advocates for an art form existing outside of the mainstream cultural institutions, challenging dominant political and cultural narratives, and he emphasizes the importance of artists and activists in diverse forms of resistance, such as street art, graffiti, and performance.

The slides present the project with a focus on visual examples of artefacts as well as aspects like the project's theoretical and methodological foundations inclusive of oppose1984in2030's contribution to the fields of critical and speculative design and some of the employed design processes and internal project constraints. Two theoretical levels are operative: one pertains to the meta-theory employed in the critical pursuit, encompassing the project's ideological and analytical stances (e.g., Agamben 2021, Elmer 2023, McDowell 2020, Prins 2022, Wood 2015, Zuboff 2019); the other concerns the domains of critical and speculative design, alongside t-shirt design and Aesthetic Resistance as instrumental tools for resisting oppressive social, political, and economic systems.

What is 'oppose 1984 in 2030' ?

'Oppose 1984 in 2030: Keeping the UN Goals on an ethical path' is an academic research and Critical Design project currently being developed at the Royal Danish Academy. This design activist project aims to criticize totalitarian policies developed in the shadows of the UN's sustainability benevolence. It involves communication design (graphic design on t-shirt artefacts) meant for circulation through living subjects and exhibition events combined with on-going critical research in the political economy of sustainability. With a duration of 10 years, the project will also be a documentation of politics and power between 2021 and 2030. A looming period that could witness the resurgence of totalitarian regimes as a powerful force shaping the world, echoing the unsettling parallels with the early 20th century.

3/10

Why This Project ?

The project name 'Oppose 1984 in 2030' is a symbolic jux-taposition of the title of the dystopian novel '1984' by George Orwell and the United Nations' resolution 'the 2030 Agenda for Sustainable Development' adopted by the General Assembly in 2015. Precautionary critical designing against undesirable future scenarios: the to-talitarian blueprints being pursued by a vast non-demo-cratic oligarchic global system of monopoly corporatism who uses sustainability discourse and legislation that point towards 1984 in 2030. Examples of control mecha-nisms promoted by entities like Rockefeller Foundation, WHO, WEF, BIS, and Trilateral Commission are biome-tric surveil l ance, digital programmabl e fiat (surveil - lance) money, personal carbon allowances, social credit points, and the destruction of small farming practices in order to create centralized controlled food production.

4/10

'Oppose1984in2030' is Not

- ***an attempt to analyze or promote sustainability visions that don't rely on global corporatist top-down management, e.g. community-based renewable energy; sustainable agriculture with local, organic, and regenerative agriculture practices; permaculture for self-sufficient ecosystems modeled after natural systems; reduction of reliance on centralized finan-cial institutions through community-based currencies and barter; cradle to cradle technology; decentralized energy sys-tems that are community-owned - the potential positive sides of sustainability.***
- ***meant to prove the existence of a global technocratic elite who conspires against most of humanity to install what could be described as a totalitarian digital surveillance technocrat-ic system. For theories and historical accounts on these oli-garchic networks, see for instance Carol Quigley (1966, 1981) and Antony Sutton (1976, 1981, 1985, 1995a, 1995b).***

5/10

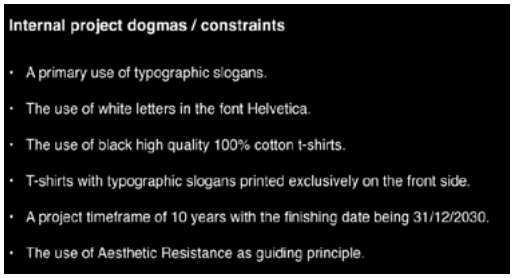
Two Theoretical Levels

A distinction should be made between two theoretical levels of the project: The first level encompasses critical design as a design field. The second level involves the meta-theory employed in the critical pursuit, the project's ideological and analytical stances.

Regarding the first level, 'Oppose1984in2030' is inspired by Critical Design. As the project evolves, there is a self-reflexive evaluation of its affinities with this type of design activi-ty, e.g. what is critical design and how is this project positioned within that field? Critical design and Aesthetic Resistance (Steppling, 2020) are proclaimed foundational theoretical inspirations but these disciplines also serve as methods: how to perform design activism through graphic design and communication design.

'Oppose1984in2030' is not about designing through preferred situations but the opposite, a warning. The speculative 'what if' elements are hyperbolic and dystopian. What if the unelected Davos billionaire's technocratic visions for humanity will be implemented? What if we the serfs will be ownerless, confined to 15-minute cities and forced to eat centrally produced and controlled artificial food that cull us off?

6/10

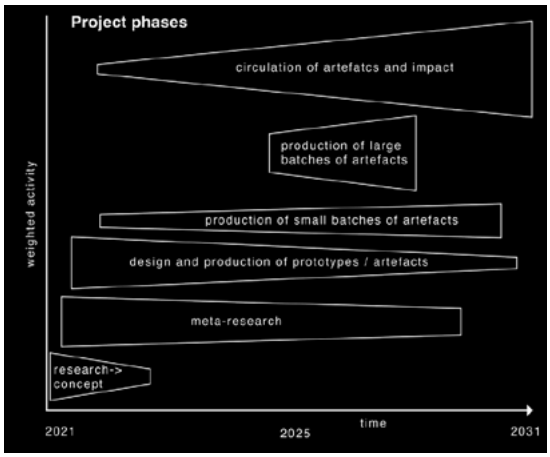


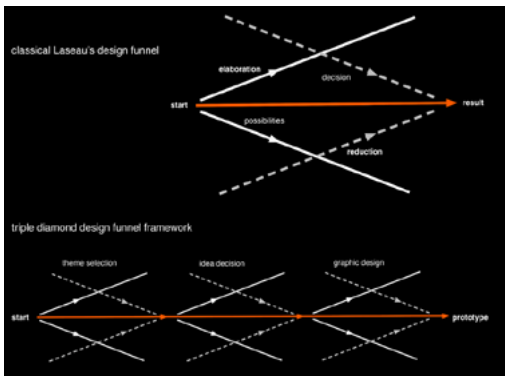
Meta-Theoretical Critical Foundations

Critical texts on global corporatist attempts to control the world economy and resources. Surveillance Capitalism (Zuboff, 2019) is the exploitation of human nature by tech-corporations who use digital surveillance technology to extract information from people. Simon Elmer uses the term 'Global Biosecurity State' to describe a 'globalist coup that is comparable to the rise of fascism in Europe in the 1930s' (Elmer, 2022). Nomi Prins' (2014, 2022) work on the power of the major banks, financial institutions and central banks serves as relevant historical background information on predatory financialization. Patrick Wood's (2015) work on Technocracy together with Jacob Nordangård's (2009) Swedish university study on the oligarchic network's influence on climate change discourse are also foundational theory.

7/10

Project Definitions





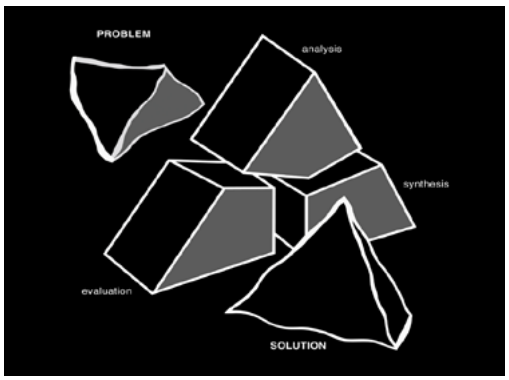


Illustration of defined internal project constraints and timeline showing the planned activities of the project. Each box's height at a given time shows the expected distributional weighted balance; e.g. in 2030 'circulation of artefacts and impact' accounts for more than 50% of the project activity.

‘THE ART OF THE INVISIBLE: PNEUMA’– EXPLORING THE PHENOMENON OF DARK MATTER THROUGH ARTISTIC SPECULATIONS.

Csenge Vass*[a]

a Moholy-Nagy University of Art and Design, Hungary
* csvass@mome.hu

DOI: 10.63442/XSRZ6259

KEYWORDS | SPECULATIVE ART, DARK MATTER, HUMAN PERCEPTION, INSTALLATION ART, ART AND SCIENCE

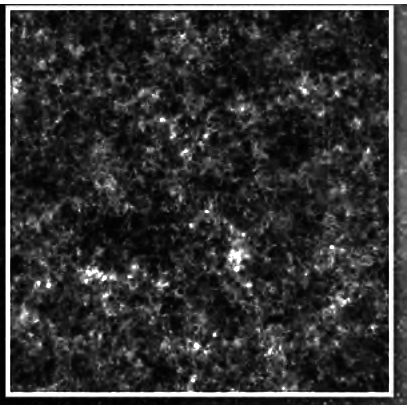
ABSTRACT | My research, called ‘The Art of The Invisible: PNEUMA’ (working title), is based on the cosmological phenomenon of dark matter. According to current models, this mysterious mass makes up the vast majority of the universe - while the material world as we know it only accounts for 5%. Science assumes that mystical matter does not interact with light but can only be perceived through its gravitational effect. Scientists can only detect this invisible matter indirectly through instruments. I aim to use the tools of speculative art to make the phenomenon of invisible matter experienceable directly to human perception. The main objective of the research is to create an experimental simulation in the form of a spatial installation in which the unknown phenomenon can be experienced through an interdisciplinary environment. It could open new and unexpected channels for human understanding, which refers to one of the main aims in the section summary, ‘More-than-human spatial complexities.’

One then might wonder, how can a perceptual interaction between the human body and invisible matter be created? In the timeless space alongside visual deprivation, the only point of reference for human perception would be matter. In this attempt, space and time would form a unity shaped by the ‘dark matter’ from within, which would enter into discussion with the human body. In the isolated situation, space, matter, and time would expand the boundaries of human perception as a non-linear entity.

The biggest challenge is to try to make an astrophysical phenomenon tangible at a more profound level. The most crucial questions in the research process are: How can ‘dark matter’ be experienced? How can the unknown take shape if we do not have the necessary material knowledge? How far can fiction and intuition go? What makes an interdisciplinary experiment a true empirical experience? Can it be collective and universal, or does every one of us decode stimuli according to their understanding? The interdisciplinary approach provides a methodological basis for understanding the work in a complex way. The different aspects of science (especially astrophysics and cosmology) and art provide an opportunity to examine the phenomenon from multiple perspectives. While physics emphasises an analytical, rational, and logical method, creative arts approach the process from a more intuitive and abstract perspective. With these tools, I aspire to create a discourse and experimental situation in which cosmology and installation art can form a common entity, bringing the abstract scientific idea closer to the spectrum of human perception.

At several points, the research is inspired by and connected to ancient Greek material theories and cosmologies (e.g., Anaximander’s theory of apeiron), various ancient mythologies about darkness (e.g., the Māori creation myth, the phenomenon of primordial chaos), the Zen Buddhist ideology of ‘vacuity,’ sensory-deprivation experiments, and the work of contemporary artists such as Yves Klein, Ad Reinhardt, Anish Kapoor, and James Turrell.

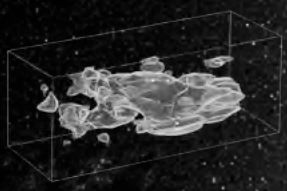
All this to say that my ultimate vision is to make the invisible material world tangible to human perception through the discipline of art.



RESEARCH FOCUS

DARK MATTER — invisible mysterious mass: **26% of the universe**

How to use the tools of **speculative art** to make the phenomenon of invisible matter **noticeable and experienceable directly to human perception?**



1

PERCIEVING THE INVISIBLE: WHAT IS DARK MATTER?

3

- Current theories claim that **dark matter does not interact with light**, but can be **perceived** only **through its gravitational effect**.
- The **filamentary structure** of this invisible matter **weaves through the cosmos, as well as the human body**. Without this defining mass, the Universe would fall apart, and so would we.
- How can dark matter **be sensed somatically**, if scientists can only detect this phenomenon through instruments?

2

MAIN QUESTIONS AND GOAL

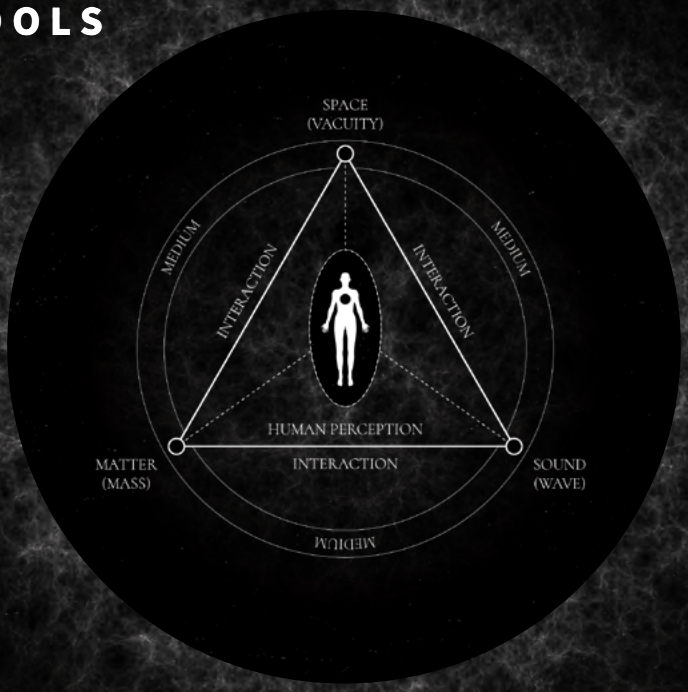
QUESTIONS:

- How can **the unknown take shape,** if we do not have the necessary material knowledge?
- How far can **fiction and intuition** go?
- What makes **an interdisciplinary experiment a true empirical experience?** Can it be **collective and universal** or does each and every one of us decode stimuli according to their **individual understanding**?

GOAL:

- Based on the relationship between **ART** and **SCIENCE:** create an **art research process** that, beyond the representation of the observed phenomenon, can help science to **understand the unknown from a creative perspective.**

4



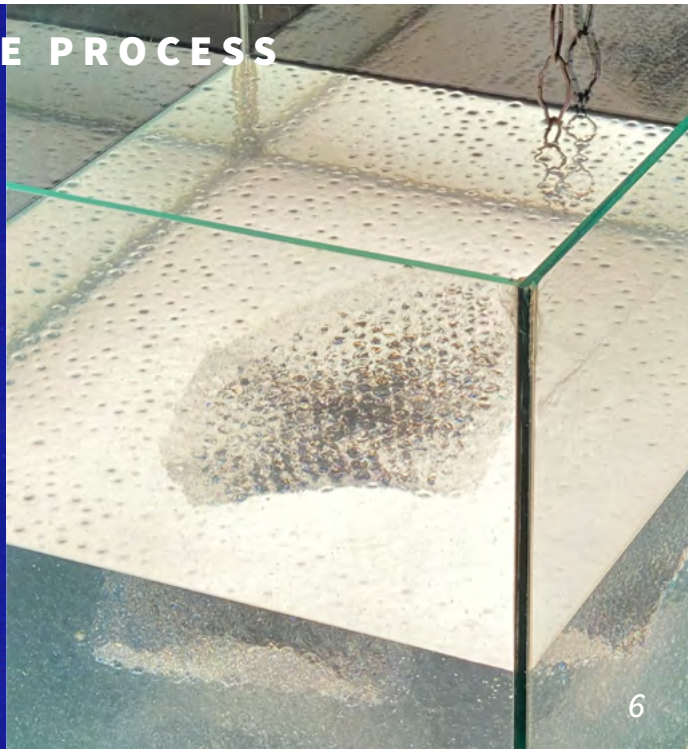
METHODOLOGY AND TOOLS

METHODS:

- Collaboration with different scientific fields and institutions
- Fieldwork: empirical data and information gathering
- Interview technique
- 'Waste-book' — researcher's diary

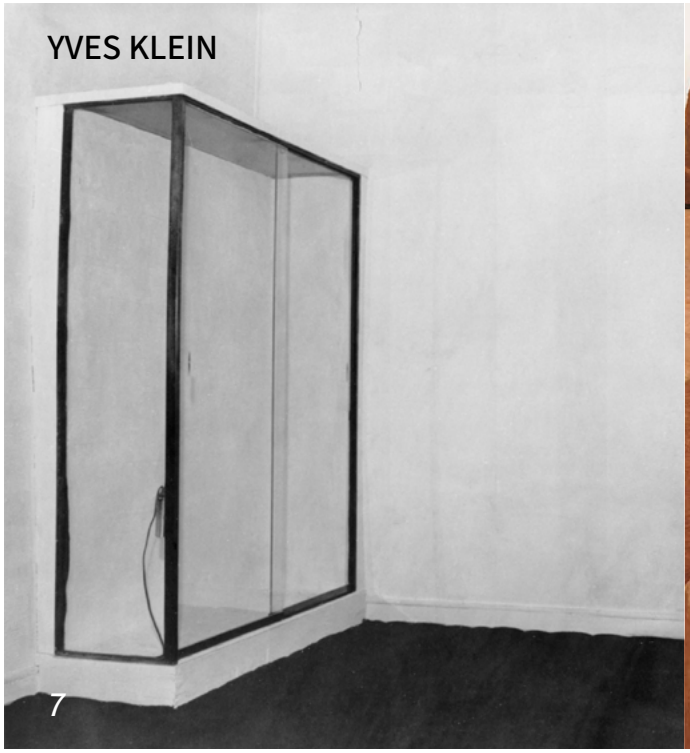
TOOLS:

- Interdisciplinarity
- Perception experiments
- Installation format



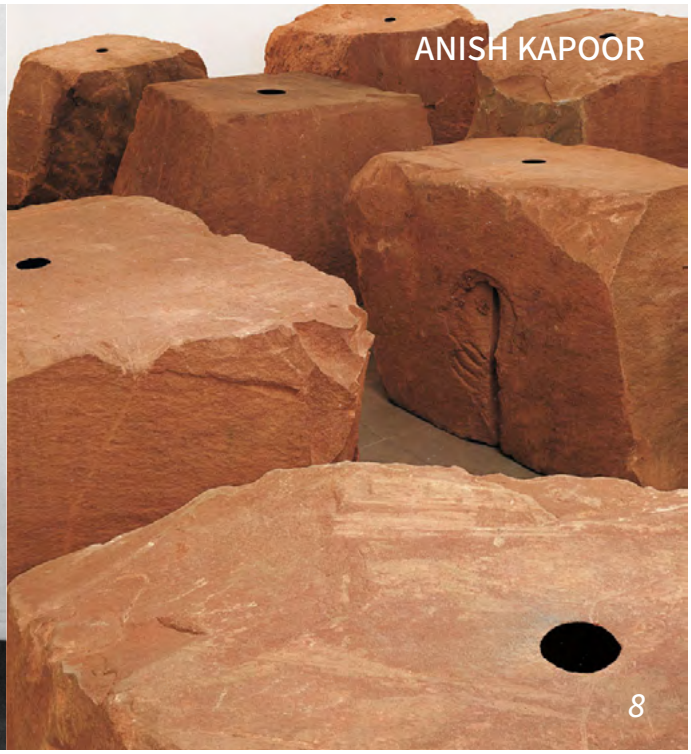
RESEARCH AND CREATIVE PROCESS

PRIORITY TOPICS IN THEORETICAL RESEARCH:



◊ **INVISIBLE MATTER** *IN* Anaximander's *apeiron* theory, Yves Klein's work, own works (URFORM/II performance-installation & APEIRON installation)

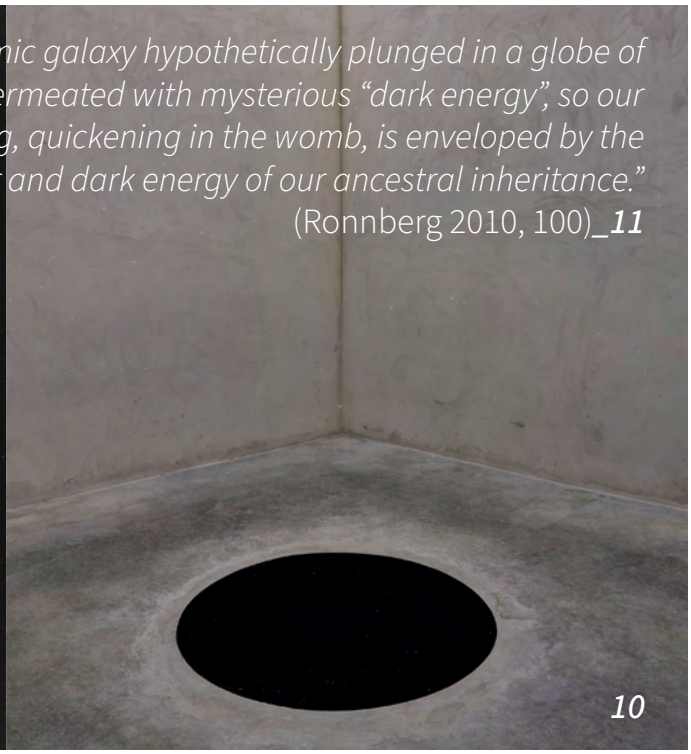
◊ **VACUITY/VOID** *IN* Vincent Keisen Vuillemin's (zen master & quantum physicist) and Yvon Myoken Bec's (zen master & philosopher) thougths about zen, quantums and intuition (interviews), Anish Kapoor's work



5

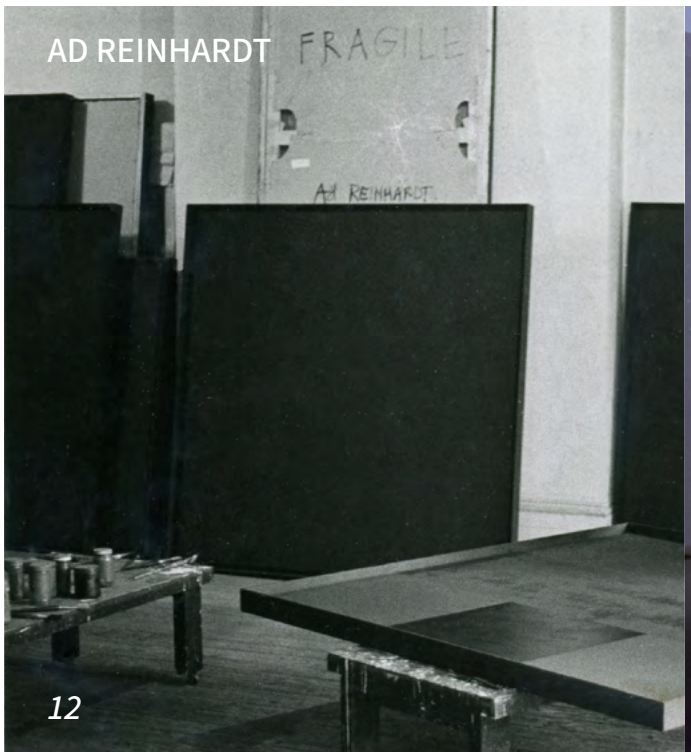
6

7



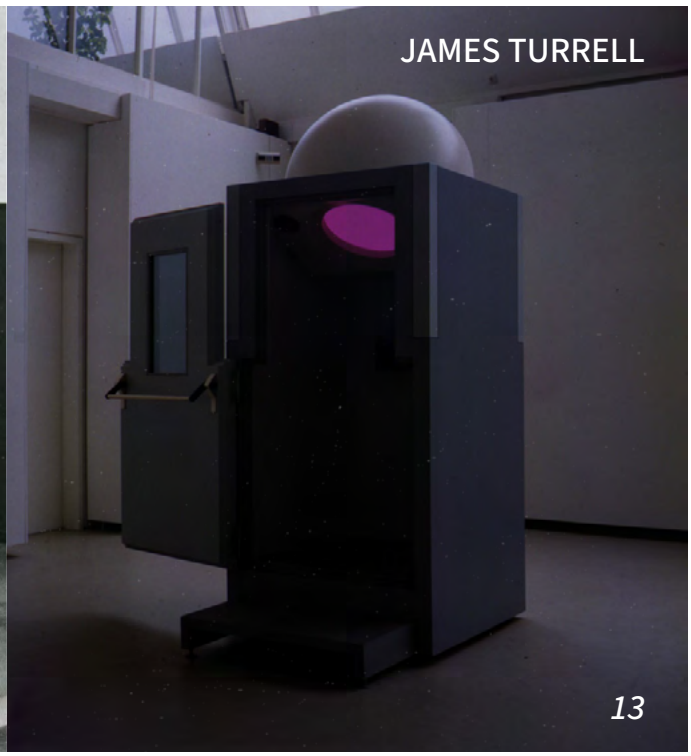
8

"Like the macrocosmic galaxy hypothetically plunged in a globe of "dark matter" and permeated with mysterious "dark energy", so our own microcosmic being, quickening in the womb, is enveloped by the dark matter and dark energy of our ancestral inheritance."
(Ronnberg 2010, 100)_***11***



◊ **DARKNESS** *IN* Symbolism of darkness, Primordial Chaos, Maori creation myth, the dark matter theory, Ad Reinhardt's Work

◊ **ART AND SCIENCE** *IN* Sensory deprivations, empirical context creation, interdisciplinarity, James Turrell's work



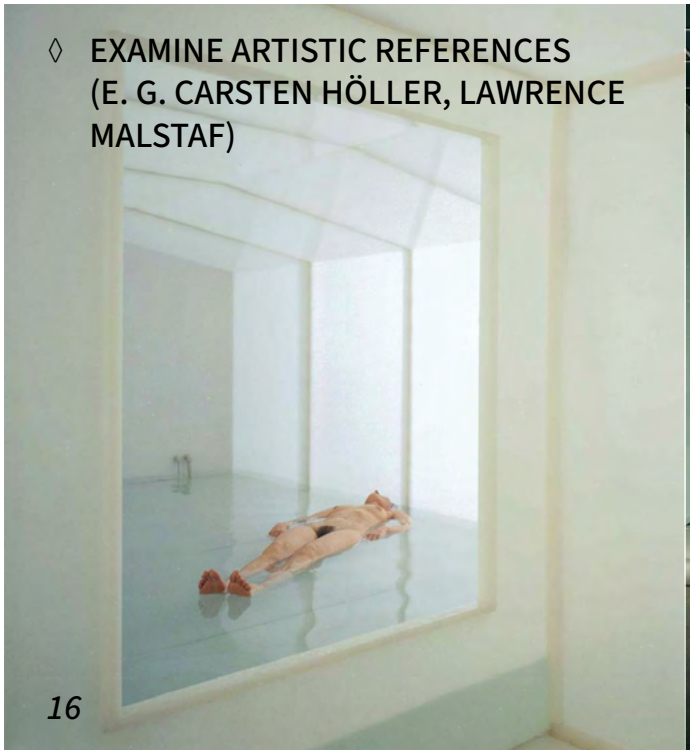
9

10

12

13

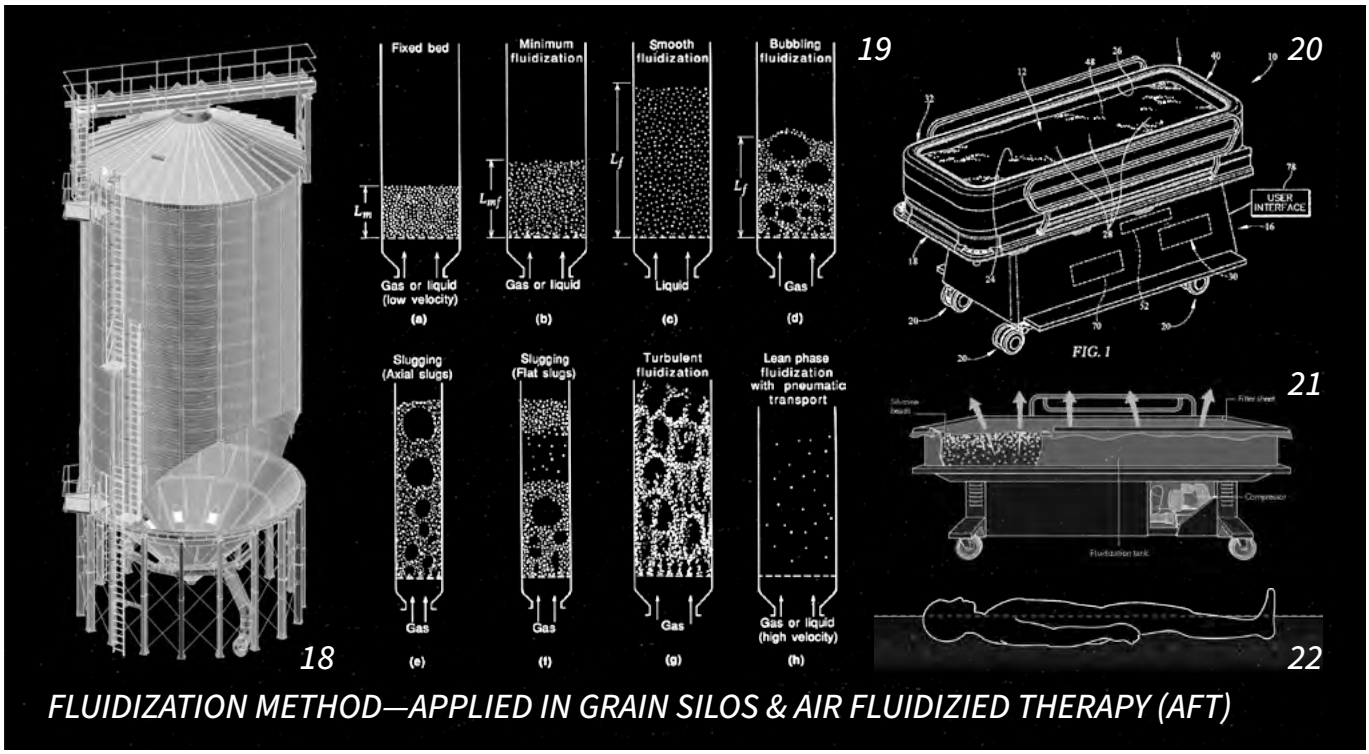
PRIORITY TOPICS IN PRACTICAL RESEARCH:



◊ SENSORY DEPRIVATION
◊ PERCEPTUAL EXTENSION

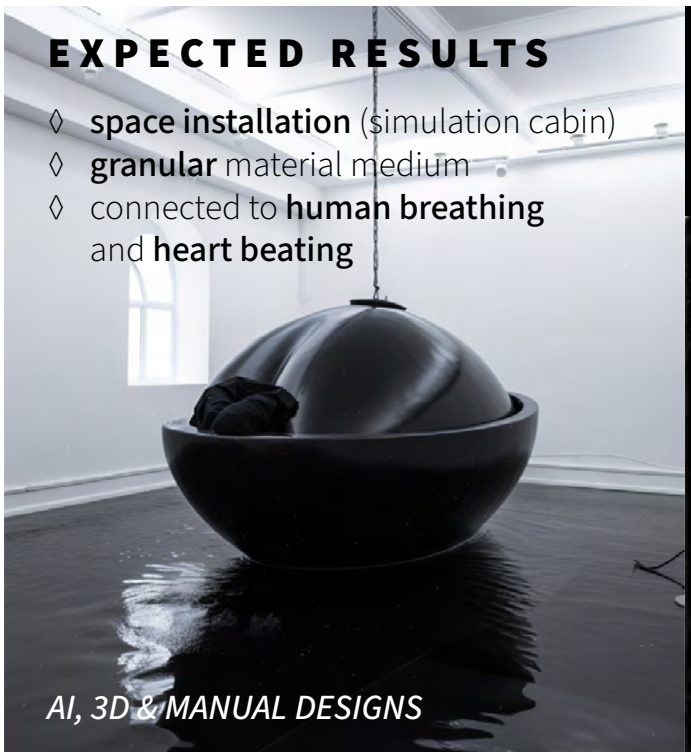
14

15

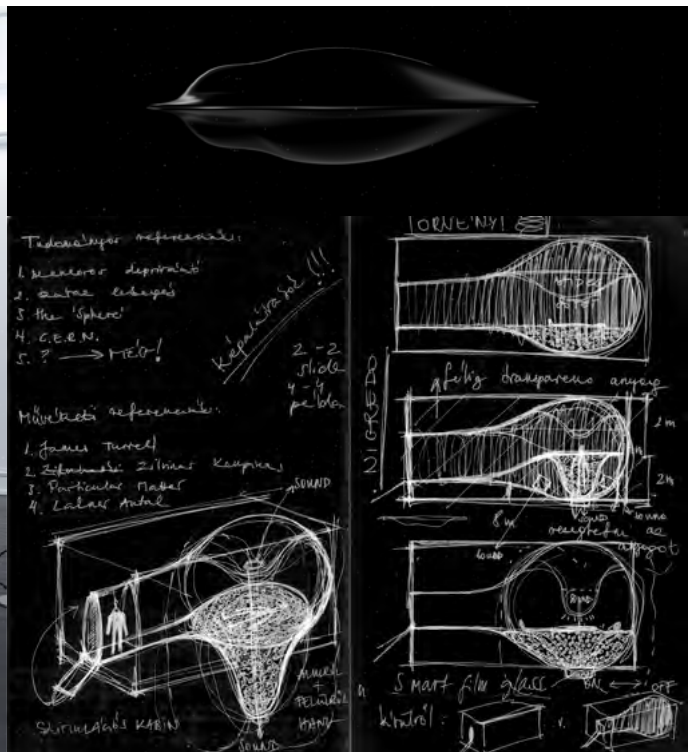


◊ EXAMINE ARTISTIC REFERENCES (E. G. CARSTEN HÖLLER, LAWRENCE MALSTAF)

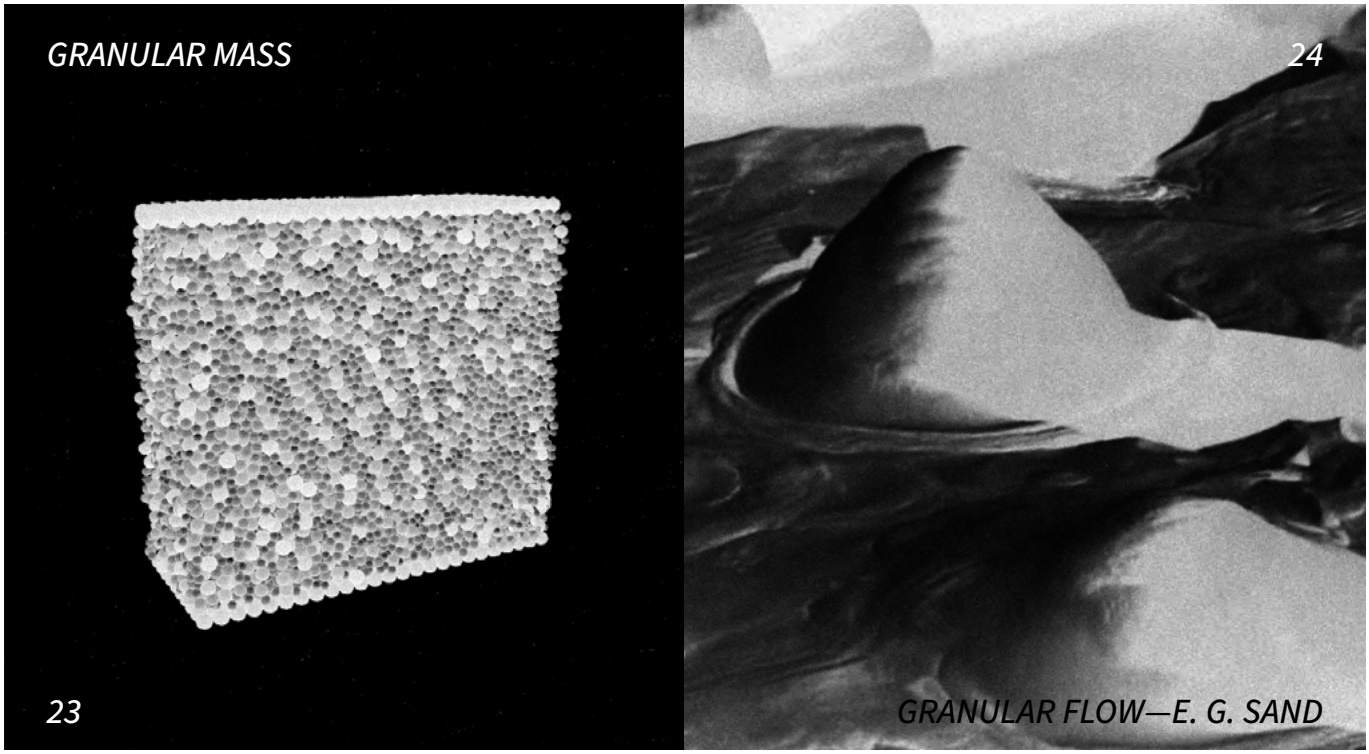
16



17



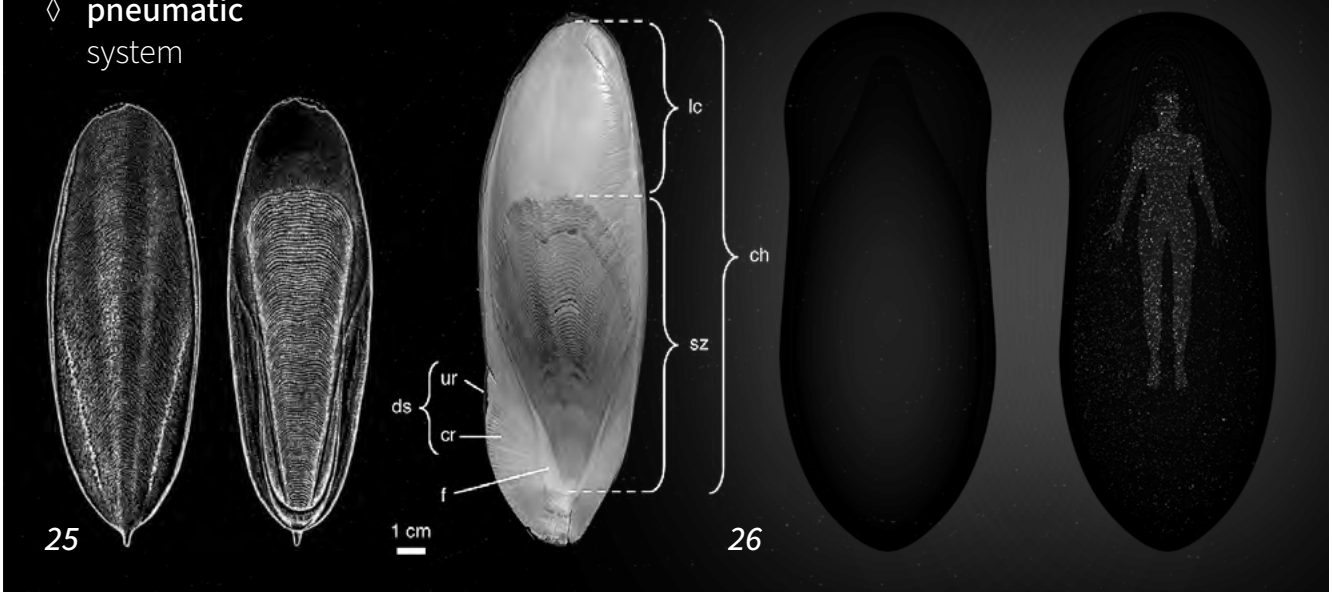
FLUIDIZATION METHOD—APPLIED IN GRAIN SILOS & AIR FLUIDIZIED THERAPY (AFT)



EXPECTED RESULTS

- **space installation** (simulation cabin)
- **granular** material medium
- connected to **human breathing** and **heart beating**

AI, 3D & MANUAL DESIGNS



FORMAL INSPIRATION: *"We are not contained within an invisible, rigid scaffolding: we are immersed in a gigantic, flexible mollusc (the metaphor is Einstein's)."*

◊ **mollusc** form (Rovelli 2016, 59)

◊ **pneumatic** system

PRACTICING ORDINARY SPECULATIONS: MUNDANE PROTOTYPES FOR MORE-THAN-HUMAN COHABITATION.

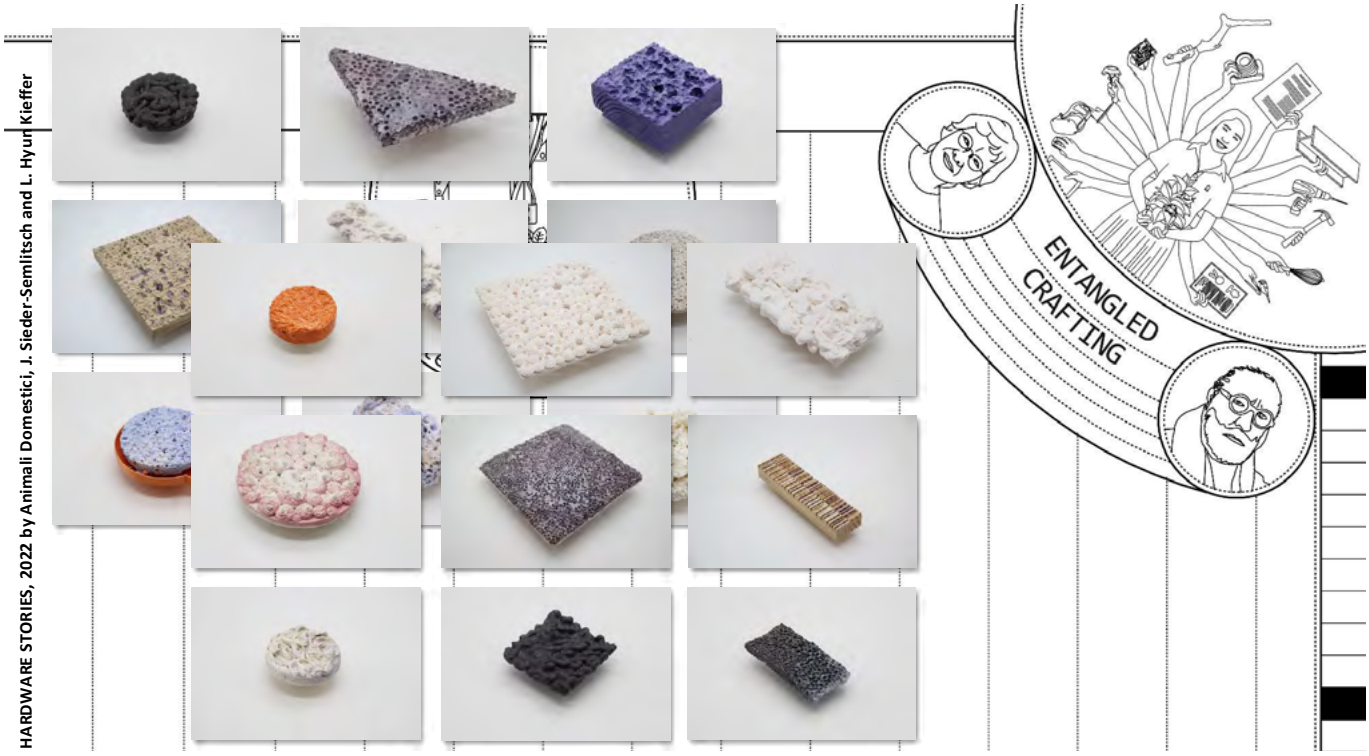
Antonio Bernacchi[a], Alicia Lazzaroni*[a]

a Aarhus School of Architecture, Denmark
* abe@aarch.dk

DOI: 10.63442/CAOW9497

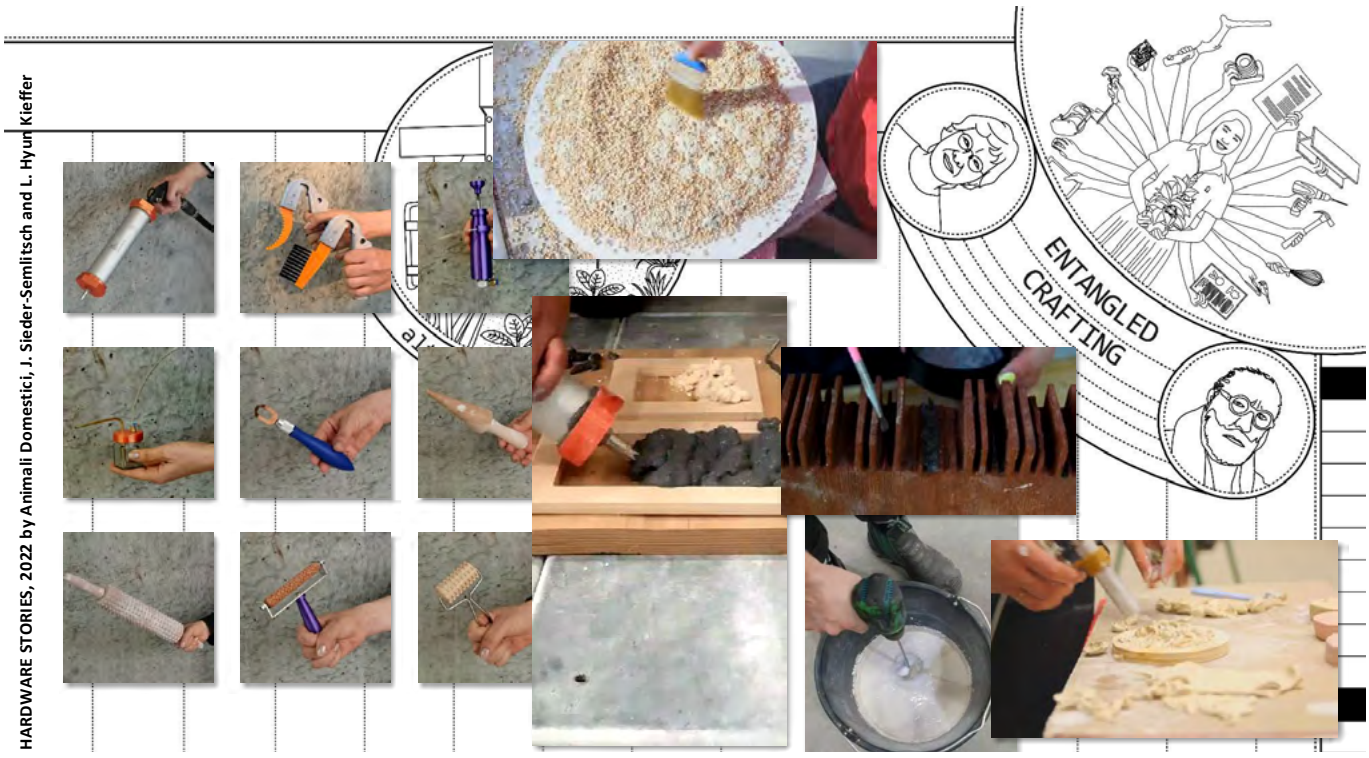
KEYWORDS | MORE-THAN-HUMAN COHABITATION, DIY, CO-CREATION, ORDINARY

ABSTRACT | In titling a book about the work of their architecture practice, “It’s small, it rains inside, and there’s ants,” F. Soriano and D. Palacios (original title “Es pequeño, llueve dentro y hay hormigas,” 2000) somehow provocatively hinted at a question at the very core of the discipline, which concerns the inclusion or, more often, exclusion of bodies and substances that were not welcome in architecture’s modernist conception of space. The cohabitation and coexistence with a wide range of non-humans is a relevant sphere for exploration, where techniques of speculative design can be very instrumental. This paper elaborates on these ideas through a critical overview of the conception, development, and dissemination of a project of speculative prototyping originally developed by the authors in Denmark for an exhibition on the topic held in 2022 in Berlin.



The project attempted to incorporate more-than-human perspectives through speculations grounded on different sources, from academic research to practical tips and hacks gathered from the web. “Hardware Stories” is a prototype of a floor, constituted by a patchwork of DIY-crafted tiles of different materials, textures, and geometry, which respond to the very diverse needs and spatial understandings of different beings, from African snails to small spiders, like barn funnel weavers.

The specificity of the Danish context, which often hosts crafting communities that exchange knowledge and experiments among friends and neighbours, shifted the perspective from a more conventional DIY to notions of Do-it-together (DIT) or Do-it-with-others (DIWO), allowing to extend of the speculation beyond an individual creative endeavor, as a form of “shared care” and collective co-creation. Manufacturing the tiles together over a long period, in weekends and marginal moments, the authors attempted to “practice” the speculation themselves first-hand, incorporating it into the sphere of the familiar and the ordinary.



To articulate methodological reflections through comparative assessment, the project is contextualized within a broader inquiry on more-than-human coexistence by the authors through previous and successive explorations.

Three other projects of speculative prototyping are recalled, in that sense, and briefly introduced for comparison through the description of material sourcing, properties, manufacturing processes, testing, and installation: a festival pavilion with artificial vegetation made of e-waste used as perching spots for dragonflies (exhibited at Venice Biennale in 2021); a set of construction details for hosting insects and mosses on the envelope of ordinary houses (exhibited at Seoul Architecture Biennale in 2020); and a second chapter of the floor project with drywall of stacked recycled bricks with soil substrate.

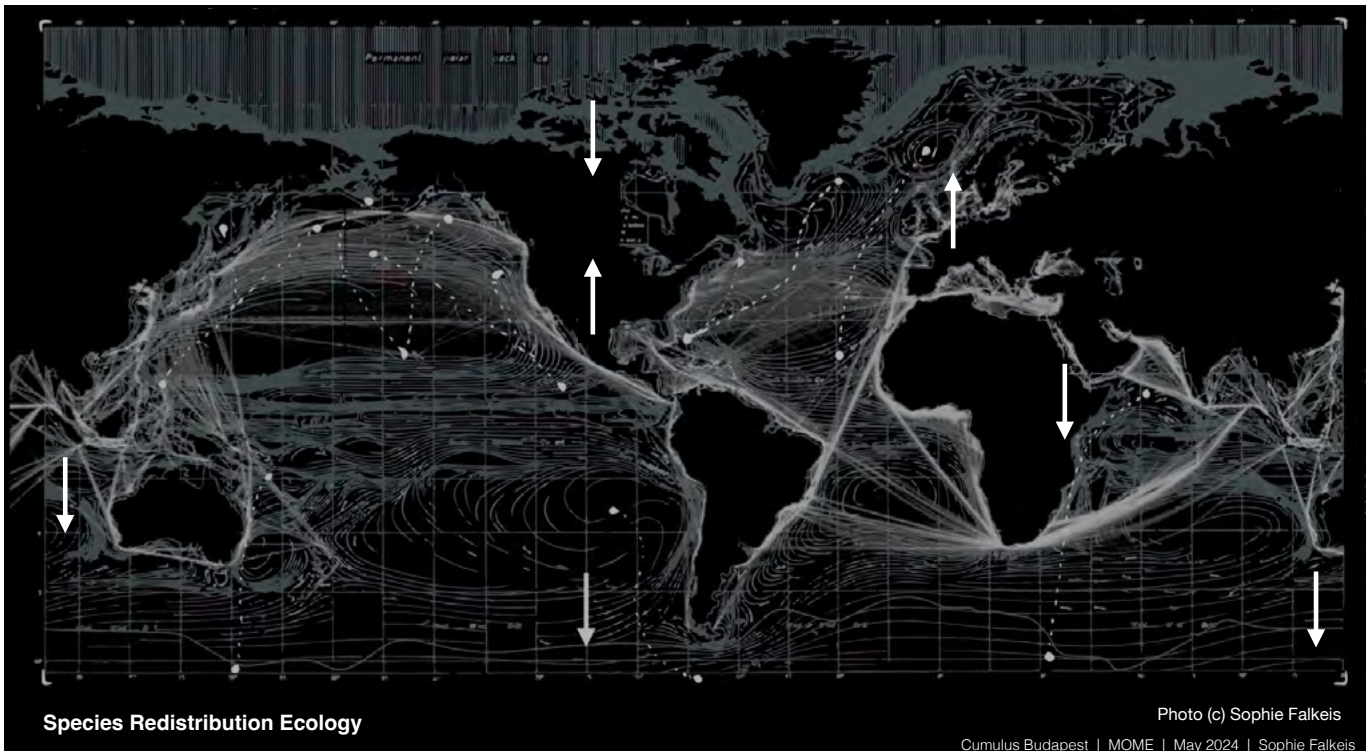
ECOLOGICAL SPECULATIONS – PLANETARY FUTURES FROM GLOBAL SPECIES MOVEMENTS.

Sophie Falkeis*[ab]

a Studio Sophie Falkeis, Vienna, Austria, sophiefalkeis.com
b The Encounters Lab, encounterslab.com
* hello@sophiefalkeis.com



DOI: 10.63442/KYYQ6472

KEYWORDS | SPECIES REDISTRIBUTION ECOLOGY, MULTI-SPECIES SOCIETIES, (ECO)SYSTEM ENTANGLEMENT

ABSTRACT | We are currently experiencing a global redistribution of life on Earth, with species shifting their habitats in response to climate change. This creates novel species interactions, as species that have evolved in isolation from one another come into contact for the first time (’first encounters’). Envisioning possible impacts on ecosystems, this talk discusses how speculative design projects explore this state of liminality through the generation of future scenarios.

In an increasingly complex world, understanding planetary inter-species dependencies and anticipating futures will be key to developing ways of living together on this planet as a multi-species society. In this process, the craft of speculation serves as an axis to explore potential futures since other futures become possible as soon as they become imaginable. Working with a spectrum of possible futures rather than predicting one singular path aims at developing ways of living in a rapidly changing, connected world and how to navigate uncertainty.

Combining “Anticipatory Ecology“ with “Speculative Design, “three of my recent works will be featured in this talk: the immersive walk-in installation *First Encounters,* the digital platform *The Encounters Lab,* and the interactive exhibition *Turning the Ecological Gears.* Investigating cascading ecological effects, these projects unravel complexity in interactive immersive installation settings. Transforming empirical facts into emotional realities through visual storytelling makes scientific research tangible and accessible to a non-scientific audience. Exploring multiple possible futures by highlighting the entanglements between natural and human systems communicates views on ecological responsibility and conveys a sense of agency.

What happens if two species
that never interacted before
are now going to encounter -
due to anthropogenically changed
climatic circumstances?

DXT—DIGITAL EXPERIENCE THEATRE: EXPLORING POST-HUMANIST DIGITAL PRODUCT DESIGN THROUGH AI AND SPECULATIVE IMAGERY.

António Gorgel Pinto*[ab], Paula Reaes Pinto[a]

a Universidade de Évora, CHAIA, Portugal
b Universidade Europeia, IADE, Portugal
* antonio.gorgel@universidadeeuropeia.pt

DOI: 10.63442/SITT4866

KEYWORDS | HUMAN-COMPUTER INTERACTION (HCI), POSTHUMAN DESIGN, SPECULATIVE DESIGN, IDEATION TOOL, ARTIFICIAL INTELLIGENCE (AI) IMAGERY

ABSTRACT | The Digital Experience Theatre (DXT) is metaphorically characterised as a rubber band ideation tool, stretching from dystopias to micro-utopias. The ideation tool is supported by a website (https://dxt.cargo.site/) with resources for the DXT workshop focusing on developing post-humanist UX/UI design concepts.

The tool is characterised by a step-by-step method inspired by Augusto Boal's Theatre of the Oppressed (TO) (Boal 2019), which, in turn, is influenced by Paulo Freire's Pedagogy of the Oppressed (Freire 2014). Freire's pedagogical proposal can be summarised as a process of critical awareness of a social reality that allows the subject to intervene in it and, ultimately, their emancipation from relations of oppression. Boal also developed his methodology based on the desire to contribute to resolving social and political problems and thought of theatre as a tool available to everyone to develop strategies to escape oppressive relationships.

Within the DXT workshop, participants, who are also users of digital products, are regarded as vulnerable human beings who must contend with many useless and redundant solutions that place them in similar oppressive situations. The DXT, adopting the TO methodology, seeks to develop innovative solutions to represent a new post-humanist design paradigm (Wakkary 2021). An ideation tool with the capacity to operate with creatives in digital technologies to contribute to the transformation of unsustainable realities by promoting the creation of digital products that are simultaneously community-based and humanity-centred (Norman 2023).

The DXT workshop lasts 120 minutes maximum, starting with a brief explanation of the main theories that inform the research, the ideation tool concept, and the workshop mechanics. It's planned for 10 to 20 participant designers and creatives of digital products in groups of between 5 and 10 elements. Each group has two conductor-designers, and the remaining elements are the antagonist-designers. The goal is to discuss dystopian ideas (Featherstone 2017, Claeys 2016) and create a set of AI-based images (Manovich 2023). The starting point is selecting a problem based on threats to the earth's ecology or societal needs affecting a community (Norman 2023). The workshop has nine steps; the conductor-designers lead the process and begin the dialogue with the antagonist designers by creating the first AI image (step one). In turn, the antagonist designers confront the conductor designer's ideas with AI imagery iterations. After the nine steps, where both sides explore and deepen dystopian ideas through dialogue and participation, the whole group must propose digital design solutions that tackle the same problem that raised the discussion.

The DXT workshop can happen in a space with a good Wi-Fi connection, where groups can gather in conversation; each participant needs to bring their laptop; at the beginning of the workshop, a few AI tools for image creation are recommended.

EMOLAB: A SPECULATIVE DESIGN APPROACH TO EMOTIONAL BIOPOLITICS IN A CAPITALIST WORLD WITH PERFORMATIVE TECHNIQUES.

Katarzyna Anosowicz*[a]

a The Aleksander Zelwerowicz National Academy of Dramatic Art in Warsaw, Poland
* anosowicz@gmail.com

DOI: 10.63442/XSSG5623

KEYWORDS | SPECULATIVE DESIGN, EMOTIONS AS A COMMODITY, BIOPOLITICAL POWER, CRITICAL PERFORMATIVE DISCOURSE ANALYSIS

ABSTRACT | “EmoLab: A Speculative Design Approach to Emotional Biopolitics in a Capitalist World with Performative Techniques” introduces a 180-minute workshop leveraging speculative design to explore the commodification of emotions in capitalist societies, incorporating performative techniques to allow participants to engage with various emotional states physically and psychologically. The workshop aims to dissect and critique the biopolitical mechanisms governing emotions, fostering immersive learning to challenge and rethink these dynamics. Through a sequence of activities, attendees will examine and embody emotions as both tradable commodities and pivotal elements of speculative capitalist scenarios, moving from abstract understanding to tangible experience and creative speculation. The journey encompasses discovery, consumption, manipulation, and the creative reimagining of emotional dynamics, employing props and performative methods to facilitate a comprehensive exploration. “EmoLab” seeks to inspire innovative thought and speculative solutions regarding emotional engagement and governance, challenging participants to envision alternative futures beyond current biopolitical and capitalist constraints.

1. Description

"EmoLab" presents a unique 180-minute workshop employing speculative design principles to delve into the commodification and manipulation of emotions within capitalist structures. This workshop integrates performative techniques, offering participants a safe space to embody and experience a range of emotional states. The aim is to critically examine and challenge current biopolitical power structures, using emotions as a lens and tool for immersive and experiential learning.

Participants will actively engage in a series of thoughtfully curated activities designed to examine, produce, and secure emotional states. These activities will not only allow participants to experience emotions as tradable and disposable entities within a speculative framework but also enable them to embody these emotions. The workshop is structured to facilitate a transformational journey, moving from conceptual understanding to physical embodiment, and ultimately to the creation of new perspectives on emotional commodification.

Utilizing the potential of speculative design, the workshop invites participants to challenge existing paradigms and envision alternative futures. This approach emphasizes the importance of performative embodiment, enabling participants to physically and emotionally experience the impact of various emotional dynamics set within speculative capitalist scenarios.

Phase 1 - Discovery of Emotions (30 minutes): This phase introduces participants to emotions as experienced in different societal constructs. Through physical movements, role-playing, and performative enactments, they explore how various biopolitical structures might influence emotional expression and perception.

Phase 2 - Consumption of Emotions (45 minutes): Here, participants engage in interactive games and improvisational activities to simulate the commodification of emotions in speculative societies. These activities, enriched with performative techniques, highlight the fluidity and tradability of emotions in different power structures.

Phase 3 - Manipulation and Control (45 minutes): Focusing on the manipulation of emotions under diverse biopolitical regimes, this phase involves exercises in empathy, mindfulness, emotional regulation, and performative reenactments. Participants gain insights into the control and manipulation of emotions in various speculative contexts.

Phase 4 - Reflection and Creation (45 minutes): In this culminating phase, participants use their experiences to develop speculative design projects. These projects aim to reimagine the role of emotions in society, challenging existing biopolitical structures and proposing alternative models for emotional engagement and governance.

The workshop employs a variety of materials and techniques, such as emotion cards, physical props, and tools for project development. This diverse range of resources ensures a comprehensive exploration of emotional dynamics in a speculative design context.

In summary, "EmoLab" offers a profound speculative design journey into the complex interplay of emotions, biopolitics, and capitalist structures, enriched with performative techniques. This workshop is an invitation to question, reimagine, and redesign the way emotions are understood and utilized in our society. Participants are encouraged to think innovatively and critically, using the workshop as a platform to consider how alternative realities and embodied experiences can inform and transform our understanding of emotional commodification and the role of biopolitical power in shaping emotional landscapes.

About the Author:

Katarzyna Anosowicz is a Service Designer, UX Researcher, and Innovation Strategist with a distinctive track record in developing the CX division at Player, a leading VOD platform by TVN Warner Bros Discovery. She established Player Labs and has successfully led over 100 projects that deepened immersive narrative experiences in streaming films and series. In her capacity at WBD in Poland, she conducts workshops aimed at redefining future media landscapes, prioritizing community engagement, and ecosystemic sensitivity. Educated with a Master's in Psychology and a postgraduate in Service Design from SWPS Warsaw, she is now completing a Master's in Theatre Studies at the Academy of Theatre in Warsaw, focusing on performative arts. Additionally, she is a recent graduate of Futures Studies & Strategic Foresight at the Copenhagen Institute for Futures Studies and will soon be lecturing on Critical Futures, Speculative Design, and Design Fiction at SWPS University. Her work is dedicated to advancing social and gender justice through speculative design. She is constantly developing her methodology centered around feminist futures, performative presence, and speculative design, aimed at analyzing spatiotemporal ecologies and fostering social and environmental change. Her passion lies in existential, total, and post-feminist theatre. She resides and works in Berlin.

KEYWORDS | UMWELT, MORE-THAN-HUMAN, SPECULATIVE DESIGN, DESIGN

ABSTRACT | This workshop is designed to explore the inherent subjectiveness of our being-in-the world. Drawing inspiration from thinkers like Bridle, Ingold, Tsing and others, it centers around von Uexküll's concept of Umwelt. In the workshop, participants will creatively explore the concept of Umwelt as a speculative design instrument through our proposed design methodology, Decentering Design. The exercises in this methodology help redefine the human position in relation to the more-than-human community through hands on observation and mapping exercises.

1. Workshop Theme

This workshop is designed to explore the inherent subjectiveness of our being-in-the world. Drawing inspiration from thinkers like Bridle, Ingold, Tsing and others, it centers around von Uexküll's concept of Umwelt (von Uexküll, 1992). Umwelt illuminates the unique way each individual perceives and interacts with their environment, emphasizing the deep connection between a being's sensory perceptions, their agency, and the world they inhabit (Lee, 2018). This results in the acknowledgement of multiple existing worlds, opening up a non-anthropocentric pluralistic worldview. Authors like Bird Rose (Rose, 2012) and others (Tsing, 2015; van Dooren, 2014) show us that we must understand these multiple worlds not as separate but as interwoven multispecies, highly localized communities.

During this workshop, participants will creatively explore the concept of Umwelt as a speculative design instrument. Our design methodology, Decentering Design, helps redefine the human position in relation to the more-than-human community in spatial design processes. The participants will explore the surrounding environment of the campus location through a series of observation and mapping exercises. The activities are divided into two main exercises. The first focuses on exploring Umwelt as a world formed by the individual's various sensory experiences within their own biological range. The second exercise challenges participants to creatively and visually approximate the Umwelt of another-than-human being. This two-fold process allows for speculations on the intersections or overlaps between human and other-than-human Umwelten, fostering a decentered experience and encouraging us to find meeting grounds to engage with the more-than-human community.

This hands-on workshop will culminate in the creation of mappings that act as artefacts, capturing and communicating the participants' experiences to a wider audience. In the concluding part of the workshop, there will be a round-table discussion where participants will share their insights and artefacts, leading to a rich exchange of ideas.

2. Target Audience

This workshop targets designers, architects and landscape architects interested in decentering their own perspective towards more-than-human perspectives. The workshop is focused on the plurality of perceptions of the environment.

3. Expected Number of Participants

We aim to organize the workshop for 10 to 20 participants.

4. Agenda

The workshop will take 180 minutes.

- Introduction 1 — 5 min
- Part 1 - observation — 60 min
- Part 2 - ideation — 60 min
- Reflection — 45 min

5. Equipment Needed

We require drawing paper, a minimum of 15 A4 sheets + 1 A4 cardboard per participant. Colored pencils, drawing pencils and wax crayons adapted to the number of participants. Two roles of paper tape. Additionally, we need an indoor space with easy access to the outdoor environment surrounding the building. In the room, we need chairs for all participants and the possibility of presenting the drawings made (tables or an empty wall).

If the campus environment has a green management plan or species inventory (planting and animals) this would help us in our preparation.

About the Authors:

Giliam Ganzevles, graduated as design researcher at the ArtEZ Institute of Arts Arnhem (NL) with an interest in global (non)-spatial phenomena and their regulations. He currently is part of Futures through Design, a research center at KASK Conservatory HOGENT Howest (BE), and is a researcher at Howest University for Applied Sciences. He employs design thinking and speculative design to explore the more-than-human and artificial intelligence. His latest research is focused on collaborative design initiatives with the More-than-Human community, particularly through their Decentering Design project.

Bert De Roo is an architect and researcher. He is part of Futures through Design, a research center at KASK Conservatory HOGENT Howest, School of Arts. He has been working as a freelance architect on self-initiated projects and for multiple Ghent-based architectural offices. He has executed research in the field of historic estates and more-than-human design and is currently exploring strategies for designers to become part of a socio-ecological community and act with care in the context of their research lab Decentering Design.

Glenn Deliège is a philosopher and works as researcher at Futures through Design, a research center KASK Conservatory HOGENT Howest, School of Arts. After having finished his PhD in environmental philosophy (KULeuven), working on the value structure of present-day preservation practices, he was involved in research surrounding the ethical aspects of rewilding (RU Nijmegen) and the role of animals in urban spatial design (HOGENT), a research line which has now broadened into a collaborative and transdisciplinary research project surrounding the role of design in a more-than-human-world: Decentering Design. Next to his research activities, he is also a lecturer, teaching landscape philosophy, animal studies and spatial design for/with animals, among other things.

Acknowledgements: This workshop was developed in the research projects ‘FUTUR-US’ funded by Howest University of Applied Sciences and ‘Towards a design methodology for the more-than-human’ funded by the research center Futures through Design. Supported by HOGENT and KASK & Conservatory HOGENT Howest. The idea and content of the workshop emerged from the fruitful conversations with Mirte van Aalst, Jo Boonen and other colleagues. We are indebted to the students participating in the workshops and classes informing this final proposal.

KEYWORDS | DISCURSIVE DESIGN, CRITICAL DESIGN, SPECULATIVE DESIGN, DESIGN ETHICS, PROVOCATION

ABSTRACT

Topic

The goal of this Format X session is to unpack, problematize, and assert the ethical, emotional, and instrumental implications and principles involved when provocation is leveraged within discursive design practice. The session involves individual, group, and guided engagements with a few foundational and practical frameworks, as well as some provocative object examples to prompt participants' re-designs that are intentionally below, above, and right on "the" ethical "line." These re-designs operate as talk-tools to generate fundamental questions and considerations for design practitioners—a forum where what-if, how-to, WTF, and LMAO duke it out.

Provocation/the strangely familiar/dissonance has been identified as a common element across forms of discursive design (e.g., critical design, speculative design, design fiction). These practices leverage ambiguity and edginess in order to get audiences to reflect on substantive, consequential topics that may run counter to entrenched perceptions and beliefs. In challenging the status quo, designers employ more radical approaches and even justify tricking their audiences—for their own "intellectual good." As discursive designs are often presented as merely speculative, as not fully functioning, and as visualized thought experiments, they can be seen as "safe" and unburdened from the common mechanisms and attitudes toward ethical oversight. "How harmful could a well-intentioned design idea actually be?" "The potential rewards certainly outweigh any risks regarding such an important issue, no?"

Despite the prevalence of such provocation over the last quarter of a century, little has been written or established about its qualities when used in professional practice. More so than advocating for explicit codes of conduct and standards of practice, vigorous, longitudinal, reflective, inclusive, and consensual debate is posited as a responsible path forward for (our) community of practice. This session is an attempt at what part of that debate might involve or help to evolve

Timing, Tools, Infrastructure, Rules

The 90-minute session involves participants receiving a packet upon entering, which includes a brief description of an ethical framework, such as the Moral Foundations Theory (Haidt and Graham), and provocative real-world artifact examples, as well as purely speculative examples. Also included are simple evaluation forms that allow for judgments along moral dimensions. Participants' responses are shared, surfacing main points of friction, and participants are placed in groups based upon their responses. Groups are guided to determine criteria to support the re-design of one of the artifact examples. Teams are assisted through cards inspired by the "dissonance dimensions" described in the discursive design literature. These artifacts are shared with the entire group with emphasis upon where an ethical "line" might be placed within one or more contexts. Rules for this discussion encourage voicing positions both openly and through anonymized written responses. Beyond the goal of robust, facilitated debate based upon specific cases and contexts, a list of the most relevant questions and principled alternatives is an expected outcome.

In the past decade, a paradigm shift has emerged, with individuals actively curating their immersive experiences. These experiential landscapes play a pivotal role in shaping people's identities and their distinctiveness as individuals. Within this evolving landscape, a central inquiry emerges: How do extrinsic influences subtly impact our daily lives, encompassing domains such as urban planning and digital immersive design? Do these influences exert persuasive forces that guide our decision-making processes in the construction of immersive experiences? And what is the role of various User Experience (UX) solutions in facilitating this phenomenon?

In this track, we aimed to uncover the references of the designers of immersive environments, whether it's a theme park or VR environment.

Many of the submissions (from various regions) tackled the role of cultural heritage and how these artifacts can be integrated in order to create compelling immersive environments in museum settings. With the rise of attention to the visitors' experience, these approaches can indicate the aftermath of the 'experience economy'

– in terms of how every experience should be re-framed as a unique encounter. These approaches help us to compare them to the traditional formats of experiencing and knowledge sharing in exhibition settings and to establish new ways of experiencing from various corners of the world. The heritage of graphic design also offers interesting approaches in several papers on designing interactions, which can lead to novel interpretations of the media of prints. The role of creating meaningful and smooth interactions is also discussed in methodologically accurate papers that dive into UX experience design and its assessment.

The prevalence of VR and new technologies are an integral part of the field of immersion studies, therefore many of the papers also describe in detail their theoretical or human-computer interaction related assessments of VR applications. Virtual architecture and the theories arising from analog approaches also have a strong influence on the field of study of immersive environments and experience design. The various free time activities and how they are influenced by our everyday technological objects were discussed (in the paper assessing musical interfaces used for jogging) (Küçükkurt & Bahar, 2024). The question of embodiment and the presence of the viewer reminds us that the specificity of immersive phenomena relies on the viewer too – as the body of the viewer should be 'integrated into the experience.' This offers a sense of uncertainty to these experiences. This uncertainty could be calculated sometimes with engineering punctuality, but this gives the sense of losing agency, while the experiencers of these aim to have the illusion of agency. This inner tension is the specificity of immersive media experiences, that operate with interactive interfaces, and that always offer new pathways for researchers to reframe their power.

The papers in this section offer novel modalities to re-interpret immersive and interactive environments and present case studies and best practices that can be used by creators and theoreticians in their future work.

KEYWORDS | LIVING HERITAGE, PERFORMING CULTURAL HERITAGE, SPECULATIVE PERSPECTIVE, THE POWER OF IMMERSION, FUTURE OF CINEMA

ABSTRACT | This paper explores the concept of 'Living Heritage / Performative Cultural Heritage,' an innovative series of audio-visual-immersive experiences designed to transcend conventional temporal and spatial boundaries. These experiences, accessible through curated apps and cinematic virtual reality (cine-VR), emerge as multifaceted tools, intertwining research, artistic practice, education, and cultural heritage preservation. The initiatives strive to foster awareness, observe sites, protect the environment, and celebrate cultural diversity by employing critical spatial practices. Inspired by the rich traditions of Situationists International, methods of urban practices assume a sensory, poetic, and critical stance in the exploration of urban spaces to stimulate curiosity, offering an alternative approach to experiencing the city.

The paper positions these projects within this theoretical framework, underscoring the imperative to deconstruct and reinterpret the city as a linguistic syntax. Furthermore, the initiatives leverage cutting-edge technologies such as VR/AR/XR, exemplifying how immersive experiences can enrich daily routines. Focused on public transport, particularly buses, and trains, as narrative protagonists, these initiatives carry histories and stories across historically significant sites.

The paper concludes by presenting two work-in-progress art-based research projects. Beyond their immediate impact, these projects endure within designated transport systems, remaining accessible to multiple users over time. The paper underscores the environmental impact, portraying the projects as instruments for promoting the knowledge of the effects of Climate Change, aligning with the vision of the United Nations' SDG, both in social and ecological dimensions. In conclusion, 'Performing Cultural Heritage' advocates for new formats in audio-visual-immersive experiences in public transport and cinematic virtual reality, presenting a compelling case for enriching urban exploration, cultural appreciation, and sustainable urban development, considering human and non-human actors and agency.

1. Introduction: Performing Cultural Heritage

As a means of expressing Cultural Heritage, we have conceived a storytelling format—a sensory and visual experience for public transport and cinematic virtual reality. This initiative aims to facilitate a process of speculative fabulation, encouraging the reconsideration and reimagining of the past, present, and future. The format presents two journeys: an audio-visual experience accessible through an app and a cinematic VR experience—a 360-degree video. These aim to guide users in discovering untold stories at familiar locations along public transport routes.

While commuting by train or bus, individuals can engage with the project via a QR code, allowing them to hear stories from the natural and cultural communities along the route. The interactive art project is equipped with augmented reality (AR) and virtual reality (VR) technologies to create an immersive experience, enabling local stories to be perceived through hearing, sight, and other senses. Based on the hypothesis that the fusion of art and technology can collectively enhance social life and serve as a tool to animate alternative sensory experiences during public transportation, a cultural heritage is performed and re-enacted. Through the narrative conveyed by various ethnicities, communities, and social groups, coupled with advancements in virtual technologies, intangible cultural heritage can be identified, interpreted, and reintroduced into contemporary consciousness.

The two projects, *Regional Express* and *Hidden Treasure Walks*, offer tours, guide participants through scenic landscapes, and collect memories of local communities. Heritage, in this sense, comes alive, as the projects facilitate engagement with the past, present, and future, enabling imaginative exploration through speculative perspectives. In her book *Staying with the Trouble* (2016), Donna Haraway advocates for a new form of storytelling, whether ‘story’ is political, social, gendered, or centred on non-human entities. To understand how our environment has shaped our society, and to address the challenges of our troubled times, characterized by a planet and ecosystem in crisis, we must provoke thought and imagine alternative ways of existence and coexistence. We have adopted Haraway's Speculative Fabulation as a method to learn and unlearn the world within worlds together. Old belief systems are reinterpreted, and new ways of living are proposed. Our format aims to stimulate new thinking through collective speculative storytelling, shifting the perspective from the human to the non-human, exploring the realms of objects, animals, and nature in a new relationship to seek answers to the pressing questions of our times, and guide us to a positive future.

2. An Audio/Visual Experience

Figure 1. Poster of *Regional Express* with QR Code that leads to the audio/visual experience on the train. Design: Ortner etc.

2.1 The Future of Cinema

The audio/visual experience is a new way of seeing and experiencing a possibly new form of cinema. The future of cinema is marked by a shift from traditional cinema to its possible future in image storytelling across a wide range of new and experimental practices. Accompanied by recent technological progress and the changing media landscape, the future cinema could transform from simply viewing a movie to participating in, engaging in, and sharing the image content, creating an alternative sensory mode. This future scenario also indicates an exit from a movie theatre to different places—to any public place or to virtual reality through VR goggles—which determines the social relation of viewing communities. The evolution of moving image storytelling changes ways of seeing and living.

A medium is not only a support or a device. A medium is also a cultural form, defined above all by how it makes us think about the world and others, through the type of experience it activates (Casetti, 2016). Audio/visual experience extends the idea of cinema, not only as an immersion in visual and sonic experience but as a confrontation with reality, enabled by technology. To gain experience also means to produce knowledge. “The re-elaboration of this reality into knowledge (to gain experience), and the capacity to manage this and similar relations with reality (to have experience)” (Casetti, 2016). Thus, the idea or function of cinema merges with site-specific theatre, playing with the cinematic space—auditory to VR environments—and merging it with the actual sites of the performance. The train or bus and the cityscape become a hybrid or speculative space between the stage, auditorium, “architectural space,” and “cinematic space,” as described by Éric Rohmer (1989, 19-29). Instead of the classic architectural setting of the black box that directs the audience’s focus on the screen and cinematic space, the immersive audio/visual experience is closer to Gropius’s idea of total theatre, with minimal physical interventions into the actual setting of the train or bus ride, which is also the site of the VR screening.

2.2 The Power of Immersion

In the contemporary landscape of entertainment and cultural experiences, immersion has emerged as a powerful tool to engage audiences on a profound level. Spanning a wide range of media, from audio-visual narratives to virtual reality (VR) experiences, immersive encounters offer unique opportunities for engagement and exploration. Whether through traditional cinema or cutting-edge VR technology,

audiences can immerse themselves in rich storytelling environments that evoke emotions and provoke thought. While the surging popularity of VR has spotlighted immersive storytelling, its foundational concepts have been explored in immersive theatre, which stands as a unique fusion of performance art and audience interaction, blurring the lines between fiction and reality by integrating actors into the audience space. Tracing its roots back to ancient performance arts such as tableaux vivant, ancient Greek theatre, and Commedia dell'Arte, immersive theatre invites spectators to become active participants in the narrative. This approach breaks down the traditional barriers of spectatorship, heightening the sense of immersion and fostering deeper connections with the performance. Therefore, the technology of virtual reality represents a paradigm shift in immersive technology, offering unparalleled levels of immersion and interaction. The spherical filmic space of cinematic VR extends traditional filmmaking techniques, providing audiences with a panoramic view of the narrative. By enveloping viewers in a 360-degree environment, VR enhances immersion, allowing for exploration from multiple perspectives.

In their *Handbook on the Economics of Cultural Heritage* (2013), Rizzo and Mignosa underscore the importance of narrative involvement in virtual heritage applications, arguing that the sense of presence in a virtual environment hinges not solely on immersion but also on narrative engagement. By seamlessly weaving compelling stories into immersive experiences, creators can enhance audience engagement and foster emotional connections.

Narrative engagement serves as a conduit between the present and the past, enabling audiences to connect with historical events and figures on a personal level. Through interaction with characters and narratives, audiences develop empathy and become more invested in the historical context, fostering a deeper appreciation of cultural heritage. Additionally, narrative engagement facilitates emotional connections with cultural artefacts and historical narratives, eliciting understanding and empathy from audiences.

By presenting stories from diverse perspectives and incorporating multiple voices and experiences, immersive heritage applications foster a more inclusive and nuanced understanding of history. Users are encouraged to reflect on the complexities of the past, promoting empathy, tolerance, and cross-cultural understanding. Moreover, narrative engagement stimulates curiosity and critical thinking, prompting users to question assumptions, challenge stereotypes, and seek out new perspectives. By presenting historical events and figures in an interactive format, immersive heritage applications encourage users to think critically about the past and its relevance to the present. This process of inquiry fosters intellectual engagement and empowers users to become active participants in the interpretation and preservation of cultural heritage. The power of immersion affects the boundaries of reality, transporting audiences into the realm of the imaginative real. By prioritizing narrative involvement and embracing new technologies, immersive experiences stimulate audience engagement and deliver meaningful connections with cultural heritage and storytelling.

2.3 Sensorial, Poetic, and Critical Urban Practices

The study of urban landscapes has become a widely debated and interdisciplinary area of great interest in urban studies, architecture, philosophy, and art theory in general. Many spatial theories have emerged since Michel Foucault’s introduction of heterotopias, places of difference, in 1967. Among them, Henri Lefebvre’s concept of spatial practice, involves regenerating sets of relations within each social formation. (Lefebvre 1974) The purpose of such spatial practice is to create knowledge of spaces and to observe sites, ecological environments, and transcultural experiences. This method of approaching the city through a sensory, poetic, and critical instrument has a considerable tradition developed by critical thinkers and artists such as Guy Debord, Michel de Certeau, and Georges Perec. They developed concepts for poetic urban space interventions, proposing practices of psycho-geography that demystify contemporary capitalist society through experimental research modes, including walking and field excursion techniques (Debord, 1995).

Moreover, Michel de Certeau's *The Practice of Everyday Life* (1980) and Georges Perec's *Species of Spaces* (1974) are practical manuals on walking in the city following psycho-geographical maps. The most pertinent aspect is that walking, as a form of bodily engagement, opens a cognitive process that can be researched. Observing, sensing, writing, and recording what is seen and heard in the streets encourage us to walk with an awareness of our environment, as humans not only yield social relations and use values but also produce their own social space—a process Lefebvre would term spatial practice. This invites us to experience the city differently, to change our perspectives and venture off the beaten track, in order to sense something new (Lefebvre, 1991). The urban space can, therefore, be full of markers that hold stories to be explored. These might be street signs, cemeteries, flood-level marks, shops, or buildings, the names of landmarks, or simply advertisements that refer to a specific area. Collecting and unfolding these fragments and building upon them are methods learnt from the Situationists. By writing the city like a text, listening to it like a symphony, and observing people's movements as choreographies, we create sensory poetic narratives. We not only walk through the city to reach a destination or consume the urban space but also become active through the 'speech act' or 'performative speech', reprocessing everyday activity to create our own discipline (J. L. Austin, 1962, 6-8). The re-process investigates a new audio/visual cinematic language based on associative principles through sounds, lyrics, and textual materials that resonate with the senses. The investigation of the city does not aim at descriptive proof but an enactment of its poetics. To capture the subliminal textures of a society through the performative is to rewrite individual stories as a poetic device according to bodily experience.

The concepts of Situationists International are still highly relevant today and are reflected in books and art projects. A recent publication by the NTUCCA Centre for Contemporary Art, *The Impossibility of Mapping (Urban Asia)* (2020), draws on these ideas. It focuses on Asia through the ideas of William S.W. Lim (1932-2023), a key architect, urbanist, and cultural figure in Singapore who attempted to imagine a future in Asia. Lim understands a city as a stage for various forms of life that interact, mix, and mingle with each other, and calls for poets and artists to celebrate an imaginative, visionary city.

To sum up, these spatial theories aim to acquire new knowledge about the world through creative, participatory, and critical spatial practice. These artistic methods continue to be influential for many artists, architects, and urbanists alike. Most pertinent here is the work of Janet Cardiff and George Bures Miller. They have created a series of audio and video walks since the 1990s using iPod, headphones, and recording guides to create narratives along the routes. The artists arranged actual backgrounds in their staged visual or audio settings to create real-life stories, blending the fictional with the actual as a 'physical cinema.' Since Cardiff & Miller, other immersive virtual guided tours have been developed. Most remarkable is the recently developed app *Seven Grams* (2021) by Karim Ben Khelifa, mixing augmented reality and animation into a journalistic project for people to understand the human and natural resources it costs to produce their smartphone. It takes them on a visual journey to Congo, Africa. The award-winning project successfully combines communication technologies to highlight the ultra-realism of the human plight of colonialism.

In the context of post-colonial thinking, counter-mapping practices can function as a tool for sharing reversal-narratives of a place, re-inscribing marginalized histories into the urban fabric and historiography of a place. African American thinker and activist bell hooks describes the margin as a space of radical openness (hooks, 15-23). Through listening to, collecting, and sharing the personal stories and perspectives on a place or the memories of significant spaces for marginalized groups within a city, this sensory experience can form an archipelago of counter-archives, becoming visible and tangible, reaching across times and neighbourhoods, and connecting the participants or audience of this audio and visual experience with people from various eras and walks of life within the complex urban structures. This practice of counter-mapping and remapping also has the potential to resist dominant narratives of entire regions with an ignored, and paradoxical history, like that of the Salzkammergut in rural Austria since the First World War.

In recent years, participatory and co-creative design and speculative research have contributed to a paradigm shift in spatial production in cities around the world, as municipalities have incorporated participatory processes into their urban agendas to re-centre the margins and create more liveable

environments in public spaces, combating heat islands and pollution (Fitz & Krasny, 2019). These co-creative strategies, like counter-mapping, can potentially increase visibility and agency, which the following case studies in Salzkammergut and Singapore aim to achieve through interviews, storytelling and filmmaking, as an epistemological shift to producing a new set of spatial relations.

3. Art-Based Research: Journeys on Public Transport in Cinematic Virtual Reality

3.1 *Regional Express* — A Project for the European Capital of Culture Bad Ischl - Salzkammergut 2024

Regional Express has been conceived as 'living heritage/performative cultural heritage,' by an international and interdisciplinary team of artists who developed a programme accessible on the train via QR Code. The audio-visual-sensory experience will be available via the Salzkammergut Culture Guide, the official app of *Salzkammergut 2024*, and through curated programmes, thus extending the temporal and spatial boundaries of the European Capital of Culture Bad Ischl Salzkammergut 2024. It offers two journeys: a primarily acoustic experience available on the train, and a cinematic VR experience accessed through VR Goggles.

Regional Express takes its name from the local train that traverses and connects the region. The train serves as the central protagonist in the narrative of the *Regional Express*. This journey carries the history and stories of various places and people. Private narratives intertwine with significant historical events. The immersive expedition extends across countryside, cities, lakes, and mountains. Nature acts as the backdrop that links personal stories with contemporary history and global transformations. The train provides the opportunity to retreat into the heart of the Salzkammergut, into the mountains, investigating the essence of its history. Simultaneously, it travels in the present moment, thus bridging the present and the past. The narratives extend beyond facts; fictions and fabulations establish a speculative connection between people and nature.

The acoustic sensory experience of space is paramount. The train resembles a journey into multi-sensory worlds that reveal the complexities of the region. The stories are always established in relation to different perspectives of narratives, nature, the mountains' inner worlds, the lake's depths, the mine, and its past. The train transports characters such as the conductor, commuters, and students who travel the route daily. The stories are unexpected, have never been told like this before, thus casting a new perspective on a pluralistic society that is itself in flux. The train in motion is a narrator, the passengers time travellers, and the passing landscape acts as the cinema. The moving train carries various connotations—it symbolizes the train of history, serves as the narrative's setting, acts as a heuristic device, and stands as an emblem of industrial progress (Michelson, 2020, p. 17). One of the earliest films made by the Lumiere Brothers, *The Arrival of the Train* (1895) marks the advent of modernity, showcasing the speed and progress of new technology. While rail transport opened the possibility of travel and tourism, facilitating trade and transport, it also played a role in the 20th century's horrors of fascism, serving as the infrastructure of the Holocaust, transporting millions of people across Europe to their fateful destinations.

In *Regional Express*, the train journey through Salzkammergut carries the narrative. The history of the landscape unfolds in a cinematic experience. Passengers become time travellers, journeying from the prehistory to the present of the region. The scenario writer Petra Ardai conducted a series of interviews with locals and collected their stories about the history and present of the landscape, nature and people, and the relations between them. This oral history and documentary material is embedded in a fictional framework of a conversation between three non-human entities: the Train, the Traunsee Mermaid, and the Mountain.

The main aim is not to reconstruct history in every detail but to build a bridge between the lives of the audience now and the historical past so that one can intimately relate to it. The researchers, including the directors, writers, actors, and participants, collectively use fictional narrative elements to change dominant perspectives and allow for a deeper understanding and personal engagement with the stories of the interviews and the region's history. While these characters—the Train, the Mountain, and the Mermaid—are non-human, they care deeply about humans and their well-being. They address passengers in human language, asking questions and offering reflections on the historical dilemmas raised in the story linked to the landscape that passes by. The Train, driven by time, faithfully follows its track; the Mountain stands firm and unmoving, and the Mermaid, a product of myths and sagas, exists only in the imagination. These characters, with their distinctive qualities, offer parallels to the people of Salzkammergut, who often perceived as traditional, steadfast, dutiful, and resistant to change. At the same time, the non-human characters' fictional view of humans creates a subversive distance and space for counter-observation, while fostering a sense of connection to the past, with stories of landscape and nature or people who lived long ago, performing a critique on anthropocentrism cantered on non-human entities. The train functions as a 'mobile monument' of modernity offering a speculative perspective of histories, where the narrative is inscribed into the historical textuality of the passing landscape along with the roaring engine. (McCalman, I. & Pickering, P., 2010, 61)

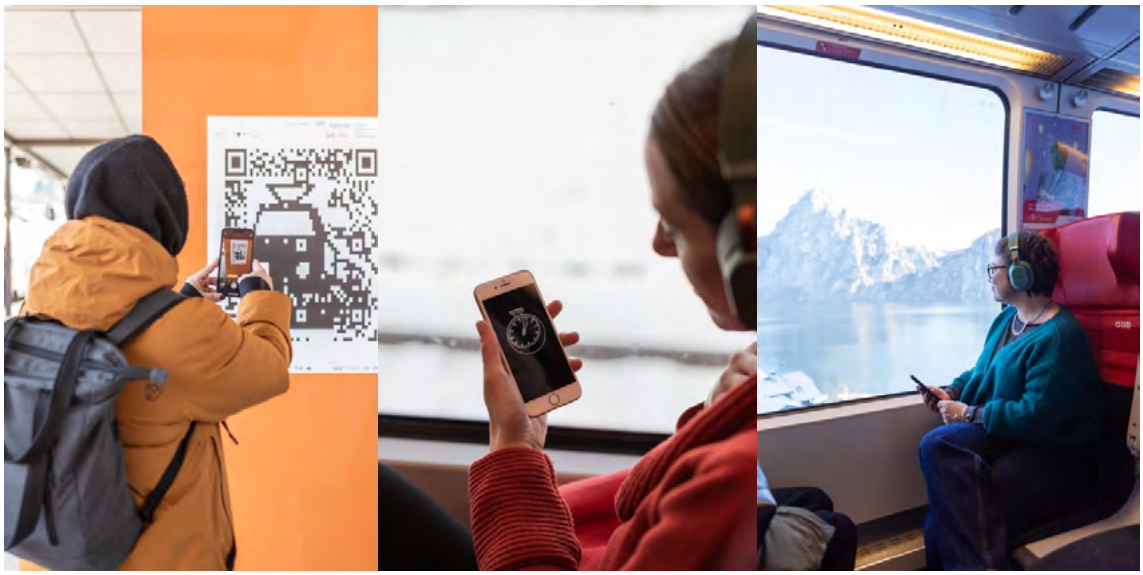

Figure 3. *Regional Express* Excursion on the train between Gmunden and Ebensee, Austria. Photo: Pia Fronia.

The train journey is divided into five excursions, each chapter corresponding to a specific segment of landscape and inhabitants. Excursion 1 [Gmunden to Ebensee] tells the story of the relationship of humans to landscape and how the existing landscape was shaped by the sea, the movement of the glacier, and the temperature changes that have created the characteristics of the landscape and its salt mines. Excursion 2 [Ebensee to Bad Ischl] focuses on the relationship between humans. The former concentration camp in Ebensee leaves its mark on the landscape, with visible traces of the stone mine shaping the mountain. Positioned along the train tracks, the concentration camp in Ebensee served as the arrival point for prisoners. Between 1943 and 1945, nearly 11,000 innocent prisoners, predominantly juveniles, perished in the camp. The segment is intercut with interviews with Wolfgang Quatember, the director of the Zeitgeschichte Museum in Ebensee, and the descendants of the survivors. For the scenario writer Petra Ardai, juxtaposing the landscape's beauty with the horrors that unfolded there was striking. Conversations with Dr. Leo Kuhn, son of the survivor Leo Kuhn, and Silvia Dinhof-Cueto, daughter of the survivor Victor Cueto Espina, shed light on life in the camp and the days of its liberation. Excursion 3 [Bad Ischl to Hallstatt] turns to the relationship of humans with their imagination, unravelling the region's importance for the Austro-Hungarian monarchy that claimed the salt-mine region as their chamber of wealth and commerce. The established and oft-repeated narrative for Bad Ischl, the summer residency of the monarchy, centres

on the House of Habsburg. To open up and change the perspective, the narrative of the *Regional Express* focuses on female leaders in society and trailblazers in their respective roles: the mayor of Bad Ischl, the director of the Saline, the Salt Factory, and Women's Forum Ebensee. Excursion 4 [Hallstatt to Bad Aussee] assembles quotes from the interviewees about the definition of Heimat and what it means for them. Excursion 5 is a soundtrack composed by Estonian composer Sander Saarmets; the way back from Bad Aussee to Gmunden allows for reflection, doing nothing, looking out of the window, immersing oneself in the train's speed, and viewing the passing landscape as cinematic experience.

The Salzkammergut is a region of tourism. In recent years, Hallstatt having been awarded World Heritage Site status in 1997, and has become as a premier tourist destination. Notably, its portrayal as a filming location in a Korean soap opera and replication as a real estate project in China, depicted in Ella Raidel's film *Double Happiness* (2014), ignited an influx of Asian tourism. During the peak season, as many as 10,000 tourists, predominantly from Asia, descend upon the town. This surge has proven overwhelming for the small community of 800 residents, sparking numerous controversies. In response, the European Capital of Culture Salzkammergut 2024 has undertaken several initiatives addressing tourism, aiming to devise strategies for sustainable tourism and the preservation of cultural traditions and architectural heritage.

As Konrad Wallinger from Kino Ebensee observes in an interview with Petra Ardai and Marlene Rutzendorfer for *Regional Express*:

> "The Salzkammergut, in the future, will resemble a colossal museum. It will be akin to a natural history museum where you gaze at the mountains, questioning their reality, whether the water is warm or cold, and if you can dip your finger in it. You purchase a train ticket in Attnang-Puchheim, traverse the landscape, examining whether there are still cows or anything else, and everything will come with a price tag. It is evolving into a colossal Disneyland, a scenario that, while not particularly prophetic, seems highly plausible." (Wallinger & Müllegger, Kino Ebensee).

Although tourism is economically vital for the region, over-tourism has become a major problem. The Salzkammergut is a closed mountain region with specific flora, fauna, and culture. Embracing new and diverse influences that challenge traditional values is essential for the region's future. However, opening up to change and admitting new values into the region's traditional monocultural social fabric, without losing its original character or damaging what should be preserved is a delicate process. The cultural and artistic programmes of the European Capital of Culture are a facilitating and mediating platform to find answers or at least to bring movement to solving the dilemma. Art, the power of imagination, can open dialogues and show ways of envisioning more inclusive and sustainable futures.

The second journey in *Regional Express*, premiering in August 2024, offers a similarly engaged outlook on the region but as seen from the future. The Cinematic VR (360-degree video) directed by Ella Raidel is an associative and sensory fabulation on the above topics. In this story, a female Asian explorer, like a retro-futuristic astronaut, returns from the future to the uninhabited Salzkammergut, which can no longer be physically visited but can only be experienced through virtual reality. The time traveller explores salt and ice caves, mountains, and landscapes. Her journey is narrated through a sequence of still images showing frozen sites and stills no longer inhabited by humans. She enters the image through a time machine that catapults her into different scenarios. Taking Chris Marker, *La Jetée* (1962) as an example for narrating a science fiction plot through still images, the explorer encounters these still images as relics from a former time; as if wandering through a museum, she transcends the epochs. Eventually, she discovers the last button shop, an actually existing shop in the town, and its owner, but this too may appear to be a dream, as no other traces of humans are present. As an example of "virtual dark tourism" this VR journey recognizes the audience as a tourist in an alien environment that takes place only in imagination and through immersive sensory stimulation as sound, images, and smell, a synchroneity of catastrophic here and now. (McDaniel, 2018, p.3)

As the explorer moves around, the audience feels, touches, and senses her surroundings along with her. The cinematic virtual reality allows us to immerse audiences in the scenario. The audio design is crucial; we

can hear and listen to the surroundings in a 360-degree range. Sonic inputs direct our gaze in different directions; when someone calls us from behind, we may turn our head and body to move towards the sensation. As we don't have legs in cinematic virtual reality, our bodies do not touch the ground as is they were ghosts and the sensation of floating can enhance the science fiction plot, though to some viewers this might create a sense of motion sickness.

To the audience, the landscape and scenarios appear like a museum, with the present time frozen and waiting to be accessed from the future. This experience draws inspiration from the film *La Jetée* (1962), in which a group of scientists undertake experiments in time travel at the apocalyptical time. As we advance with VR technology, VR goggles have a similar function as the time machine, helping us transcend our reality and immerse into the audio-visual surroundings to the uncertain temporal space. As technology lineally progresses, a messianic future scenario should be inscribed with the presence of our physicality in a virtual environment, where we could immerse ourselves *as if* we were in dream, or we could wake up in the horrific reality that humans have caused.

3.2 *Hidden Treasure Walks* — A Virtual Immersive Cultural Experience in Singapore

Hidden Treasure Walks (2024-2027) is a consecutive art-based research project that aims to offer an immersive experience from an app and a 360-degree video, to guide its users to the discovery of untold stories at familiar locations along a bus route in Singapore. Using the field findings from the natural and cultural communities around the route, the research combines AR and VR technology to produce an immersive experience for local stories to be heard, seen, and sensed. Besides raising awareness of Singapore's rich cultural heritage, *Hidden Treasure Walks* exceeds traditional artistic limits and operates on the hypothesis that art and technology can jointly improve social life. Through the narrative of sensory inputs, voiced by different ethnicities, communities, and social groups and equipped with new virtual technologies, the intangible cultural heritage of hidden treasures in Singapore can be identified, interpreted, and reintroduced. The project explores the city as a spatial practice, reflecting our subjective relation to ecological, urban, social, and cultural surroundings. The virtual experience will take place on a bus and through a walking tour of nearby communities and historical sites, exemplifying how art can engage the mind, and deepen our understanding of what lurks in everyday environments. The research project aims to deliver two results: (1) An app called Hidden Treasure Walks (HTW), designed as a GPS-triggered audiovisual guide. The soundscape is the main carrier of the narrative experience, punctuated by a site-specific AR experience. (2) A series of 360-degree videos based on the same story. Participants can access cinematic virtual reality episodes without being on the site.

This project creates awareness of Singapore's cultural heritage and collective social memory through diverse oral traditions and stories that foster local identities. The sense of belonging is inspired by awareness through connecting art, technology, and people. The app, HTW, will be developed in such a way that it serves as a walking guide, immersive storytelling experience, and an educational resource on cultural heritage. The app works through GPS location markers and will prompt related content to the user. This interdisciplinary project—including field knowledge from architecture, urban studies, sociology, and cultural history—combines art forms such as cinema, theater, music, and communication technology in AR and VR. It aims to document a vanishing past, preserve collective memory, and imagine a possible future of life in Singapore. Through research, communities and social groups of diverse cultural backgrounds will formulate a collective identity for creative and artistic interventions in a fast-changing urban space.

4. Conclusion: The Spatial Practice of Sensing Places

Through performing cultural heritage, these two art-based research projects offer an audio-visual sensory experience in a digital format that allows participants to connect to the unique identity of a place. The main aim is not to reconstruct history in precise detail but to traverse between the past, present, and future, and to offer alternative perspectives that audiences can not only relate to intimately, but also be alarmed to foresee. The storytelling provides an alternative way of seeing and listening to the spaces we inhabit, engaging in an otherworldly experience through cinema and the post-cinema of portable devices. The passing landscape visible from the windows of public transportation offers a supplementary cinematic experience and acts as a real backdrop to the fabricated temporalities of the audio-visual experience, in which participants transcend the present and fully immerse themselves into an imaginary audio/visual landscape of future.

These projects provide an alternative way to explore, walk, and experience the city using highly accessible mobile devices. Instead of acknowledging consumerism, the audio-visual journeys awaken the curiosity of discovering unfamiliar and lesser-known sites. These immersive journeys are, in effect, the spatial practice of remapping our sense of a place, based on the dialectical relation between the imaginary and the fixed reality. Beginning from a familiar place, these journeys carve a path through time, prompting us to discover, decipher and decode the histories and stories of places. Participants become active producers of one's own space, and the spatial practice in turn influences the individual in many ways. Through an approach that marries art and technology, the projects offer many entry points into research, artistic practice, education, and cultural heritage, and are intimately connected to the biosphere of local communities.

Rather than retreading the existing narratives of a space, novel stories of a space are thus told, and fresh modes of experiencing society produce anew the spaces we inhabit, affecting how we perceive a space. By counter-mapping the places that already bear the traces of colonialism, global conflicts, and omnipresent governance, forgotten stories can be reintroduced into the urban fabrics of lives. What Karl Marx said, "The forming of five senses is the labour of the entire history of the world down to the present," can hold true today, through the generation and redistribution of five senses through immersive technology. Individuals and communities can deepen their pride and find their roots in the native land by incorporating stories that were previously ignored or marginalized, never heard or seen, thus recovering more complete histories to be integrated into the virtual present.

About the Authors:

Ella Raidel is a filmmaker, visual artist and Asst. Professor at ADM School of Art, Design and Media, NTU Singapore. Her interdisciplinary works focus on the socio-cultural aspects of globalization, urbanization, and image representation. She experiments with alternative and hybrid formats and materials, exploring innovative paths in creation.

Marlene Rutzendorfer is an architect and curator. She has been developing formats of architectural mediation and interactive urban research, participatory design, and construction of exhibition architectures with the platform for architecture Wonderland.

Benjamin Seide is an expert in the field of computer animation and immersive media and Associate Professor at ADM School of Art, Design and Media, NTU Singapore. His research investigates novel approaches of state-of-the-art technology (VR) particularly in the area of virtual cultural heritage.

KEYWORDS | CROSS-MEDIA, CROSS-MODALITY, HAPTIC RHYTHM, HUMAN BODY INTERACTION, SYNCHRONY

ABSTRACT | The diffusion of digital and digitized environments enables the increase of possible readings of space. At the same time, the development of wearable devices enables the body to multichannel interface. The research is inscribed in scientific and design reflection that explores the relationship between digital information and the human body. Through multi-channel modality, the scope of the project can act cross-modality on perception and cross-media on information. Following the development of research on the channel of touch and the technical possibilities related to the development of tactile communication on the body's surface, the research chose to carry out an experiment dedicated to the relationship of this sense with sight. We then introduce the phenomenon of rhythmic synchrony as a perceptual tool for creating a sense of immersion and attention management. After defining the properties of a cross-modal and cross-medial rhythmic signal, two experimental tests were carried out to verify the signal's effectiveness on perception. The test results show that cross-modal rhythmic stimulation has a good ability to direct users' choices. The experimentation lays the foundation for further research in cross-modal synchrony as an element of engaging people and supporting decision-making and attention processes in digital information-dense environments. Subjects' choices to synchrony effects highlights the opportunity for applications designed to increase the connection between the body and the interface in immersive experiences.

1. Introduction

In the contemporary context, in which the presence of digital technologies is becoming increasingly pervasive in real and virtual spaces, the physical and cognitive relationship aspects between the body and artifacts becomes an important element of interaction and communication processes. In this context of transformation, the body in its perceptual and motor complexity increasingly becomes a direct interface to digital services (Zannoni, 2022). The interface body can communicate through bidirectional processes of information exchange with the space it relates to and crosses in the architectures in which it lives in its daily life. These transformative scenarios, in which a pervasive relationship between human and machine emerges, are gradually introducing new design visions that have been identified with the term *Ubiquitous Computing* since the late 1990s (Weiser, 1999). In these, the quality of the relationship between tools and spaces augmented through the integration of digital services often results from the multisensory characteristics of the designed interactive systems. Spaces and devices that offer a digital experience increasingly have quality objectives proportionate to their ability to dialogue with the body using multichannel communication. This is also demonstrated by the fact that the research and market for technologies is increasing year by year and the amount of projects that take into account multisensory aspects in interaction processes. The rapid growth toward the integration of digital technologies in everyday spaces highlights on the one hand the possibilities of hierarchizing more of the information sent to people, and on the other hand it allows for imagining systems capable of making information more accessible. The museum setting is a relevant example on how multichannel information can be articulated by meeting needs related to the perceptual difficulties of categories of users (Eardley, Mineiro, Neves, & Ride, 2016).

An increasing number of digital environments are coming into common use. Examples are places designed for learning complex procedures (Sowndararajan, Wang, & Bowman, 2008) or for the health care setting (Bateni, Carruthers, Mohan, & Pishva, 2024). Frontier of the field that investigates multichanneling in partial or full immersion scenarios is that of e-sports and simulators. These applications aim to reproduce with high quality standards real experiences in controlled and distant spaces. In recent decades, multiple wearable or hand-held devices that integrate haptic perception have been experimented with to simulate real pressor experiences on our bodies. These experiments have been introduced into multiple commercial products becoming an established media channel recognizable by users (Lederman & Klatzky, 2009). The field of gaming and simulation are the most popular commercial vectors of these trends. In support of immersive design, two concepts support reflections on how enabling and emerging technologies should be more investigated from a multisensory perspective: cross-modality and cross-mediality.

We can consider cross-modality in this context as a mechanism through which sensory information is processed and decoded by the brain by exploiting features related to spatial proximity and synchrony (Balconi & Carrera, 2008). The convergence of congruent and simultaneous stimuli between the senses allows for the identification of recursive patterns that the body reads based on its prior experience and in an automatic manner. From the point of view of the design domain, this notion allows us to understand how important it is to consider the design of experience as a system where the body is always involved with all its parts and that any sensory information has repercussions on the entire perceptual and cognitive system.

At the same time, the cross-media introduced in the 1970s in the literature starts from the assumption proposed by Marshall McLuhan (1964), in which media are a translation of ourselves and an extension of our prosthetic system. With respect to this assumption, in relation to the contemporary technological debate, if we consider that most adult people use a smartphone on a daily basis to communicate and connect to the web, it is plausible to argue that these devices are an extension of our body. Media systems thus establish a symbiotic relationship with the body and modify the human perceptual and communicative capacity. Cross-mediality becomes evident in the integration with devices and media from the moment we have "hooked up" to the network and its services, speeding up more and more the processes of communication at a distance (Bauman, 2002) and delegating part of our memory to these devices (Bagnara, 2006; Bannon, 2006; Flusser, 1990). Concerning the evolution of the tools available to humans in the processes of relationship between interactive systems, regardless of whether they are

artifacts or spaces, it becomes crucial to investigate the role of haptics not only from the perspective of perception but in relation to design scenarios in the field of design. When we do not have direct human-machine relationship action mediated by an interface, in many cases the modes of relationship are naturally configured by activating automatic and uncontrolled cognitive processes. Tactile vibration and recognition of pressure rhythms fall into these case histories becoming interesting areas in the development of innovation in both real space design and emerging extended reality (XR) technologies.

2. The Relationship Between Haptic Languages and the Body

The sense of immersion and emotional involvement of people are among the aims of those who design digital or digitized environments. Among the characters that support these goals, multichannel information is an effective tool for hierarchizing content over time and providing feedback that increases the quality of control of the proposed scenario. In digitized environments involving more than one person, the channel of touch shows optimal qualities to increase the sense of immersion and emotional involvement in the experience. Acting on the surface of the body, thanks to an established development of wearable devices (Zeagler, 2017), the touch channel is distinguished by the quietness and invisibility of messages; these allow a high level of privacy to be preserved for the people receiving them (Jones & Sarter, 2008). Finally, the tactile channel, under conditions of sensory disability, can support perception by integrating information on the body surface (Shull & Damian, 2015).

The tactile channel can be used for complex information thanks to the diversity of stimuli it is capable of collecting-pressure, vibration, temperature-and the variations by which the same can be modulated-intensity, frequency, rhythm, pattern, symmetry with the body.

The complexity of haptic languages is further powered by the correspondence of the stimuli delivered with people's previous sensory experience. Indeed, research indicates greater perceived pleasantness in stimuli such as pressure than vibration (Pohl, Brandes, Ngo Quang, & Rohs, 2017), which is more foreign to the body's experiences in the world. The perceptual relationship of haptic messages on the body, however, has not only obvious potential with respect to the composition of messages on the surface; in fact, the literature shows how the use of haptic patterns in synchrony to other messages can support comprehension of written communication (Rovers & van Essen, 2004) and have emotional effects on receivers (Baumann, MacLean, Hazelton, & McKay, 2010; Koch, Fuchs, & Summa, 2014).

The types of information delivered through human-machine haptic communication is broad, as is the complexity with which languages can be constructed. To create codes that are recognizable by the human body, some research uses patterns of vibratory stimuli called *Tactons* (Brewster & Brown, 2004; Brown, Brewster, & Purchase, 2006; Brown & Kaaresoja, 2006; Brown & Kaaresoja, 2006; Barralon, Ng, Dumont, Schwarz, & Ansermino, 2007); others use patterns of pressor stimuli called *Pactons* (Zheng & Morrell, 2012). Finally, others use mixed systems of stimuli that alternate or work simultaneously (Kim, Castillo, Follmer, & Israr, 2019).

More complex codes ambition to tactually translate precise letters or phonemes (Enriquez, MacLean, & Chita, 2006). Other studies, on the other hand, aim to compose semantically simpler information and use stimuli to induce the body to react consciously or unconsciously or to suggest behaviors in space. In particular, several studies emerge in this regard that exploit haptics to support orientation in space through direction signals delivered in the sole of the foot (Frey, 2007; Velazquez & Pissaloux, 2014). An interesting solution has been studied in the automotive field to communicate the presence of cars in vehicle blind spots through haptic signals delivered on the surface of the steering wheel (Ploch, Bae, Ju, & Cutkosky, 2016). Previous studies by the authors show how it is possible to exploit haptic rhythmic variations to draw human attention to specific points on a pathway (Dall'Osso, 2021) or use a rhythmic pressor signal to unconsciously shift the body's center of gravity forward or backward at a given time (Dall'Osso, Zannoni, & Licaj, 2022). In all the haptic languages recalled in this concise examination, the rhythmic component plays a primary role in structuring sensory qualities. In his studies on form and figuration Paul Klee names touch among the

senses that have the capacity to recognize rhythm consciously (Klee, 1959) or unconsciously. People have a habit of rhythmic perception that is consolidated from the body's earliest experiences in the world and then refined over time. Human reactions to the presence of rhythm are natural and cross motor, social and perceptual behaviors. Rhythmic entrainment is, for example, one of the most studied mechanisms of the human-rhythm relationship. Rhythmic entrainment occurs when the body, in the presence of a specific rhythmic stimulus, changes its behavior unconsciously and tends to move closer to that specific rhythm. Rhythm entrainment is well known in the relationship between movement and hearing so much so that studies and smartphone applications show how certain music can modify movement performance (Moens, van Noorden, & Leman, 2010; Moens, 2018) or generate feelings of calm (T. Azevedo et al., 2017). Thus, rhythmic entrainment can be said to be a natural human tendency to seek synchrony with a perceived external rhythm in the surrounding environment or people in proximity.

In the technological-digital domain, the sense of touch associated with synchrony effects is evident in numerous commercial products. Primarily, these are vibration actuators used inside phones and smartphones that are activated in synchrony with the ringtone to reinforce human attention-getting. Similarly, joysticks use vibratory systems to communicate to players sensations related to the scenario proposed in the video monitor. The evolution of devices related to digital sports shows in the contemporary the highest degree of complexity related to the use of haptic stimuli. Dedicated e-sports workstations, in fact, use diegetic or mimetic interfaces (Calleo, Dall'Osso, & Zannoni, 2023) where haptic stimuli synchronized with the video or VR experience increase the sense of immersion. This effect is achieved by stimuli that go to characterize digital elements and by the synchrony between haptic feedback and body movements poised between real and digital space.

In the product sector dedicated to private homes, two interventions on the sofa object that use haptics in a different way in sync with video are worth mentioning. The first is the *Miliboo smart sofa*[1], a sofa with a grid of vibration actuators, speakers and RGB lights integrated into the seat. Through the multichannel system, the sofa offers sensations synchronized to the video experience that is present on the television. A less recent project is *Immersit sofa*[2] (2017), a platform on which to place the feet of a generic sofa. The platform, thanks to motion video conversion software, inflates and deflates by moving the sofa on the three Cartesian axes. The resulting effect is a home station that moves in synchrony with the digital movie or game, causing a strong sense of immersion in the user. Thus, in the digital environment, synchrony is an effect that causes a strong sense of immersion and allows the user to perceive details of scenarios with a sense of reality. Following the concept of cross-modality, the synchrony proposed by the stimuli of digital devices has effects that cut across the entire experience and act on both conscious and unconscious levels.

The literature review did not highlight the design use of video-aptic synchrony for specific environments. Imagining technological applications related to *Ubiquitous Computing* contexts, it seems evident that the human body needs the development of tools to support attention and choices among multiple proposed interfaces. The potential of the rhythmic component as the basic structure of a cross-modal, cross-media language becomes the focus of the present research, particularly in the dimension of the subject of cross-modal synchronic information.

3. Cross-Modal Rhythmic Synchrony for Attention Activation

Within the problem field circumscribed in the introduction and following the review of scientific literature, the research focuses on the potential of rhythmic synchrony as a tool for supporting spatial attention. This, within current and future scenarios in which the human body is immersed in VR scenarios or *Ubiquitous Computing* and AR environments. The synchrony investigated by the research is cross-modal and cross-media.

[1] https://www.miliboo.com/smart-sofa.html

[2] https://www.kickstarter.com/projects/423274566/immersit-awesome-motion-and-vibration-device-under

Cross-modal synchrony refers in the coherent connection between two stimuli on different sensory channels, sight and touch. Cross-modal synchrony is activated through a coherent rhythmic message between the video present in the space and the vibratory signals sent on the surface of the person's body. With the aim of generating clear answers that can be a tool for future research advances, two tests were designed and conducted. In the tests, the objective was to determine the effectiveness of rhythmic synchrony in influencing a choice with or without disruptive elements. Repetition of the tests then aimed to understand whether prior experience can help in understanding synchrony.

Further objective of the research is to identify application possibilities related to the use of cross-modal and cross-media rhythmic synchrony with respect to wearable or body-contact devices under conditions of use.

4. Experimental Tests

In order to assess the quality of synchronic cross-modal rhythmic stimulus, two test protocols were designed. A total of 20 people ranging in age from 22 to 37 years participated in these. None of the people had apparent perceptual problems in the sense of touch and vision. A proportion of 65 % women and 35 % men took part in the test. Of these testers, 18 said their dominant hand was right-handed, 1 left-handed, and 1 claimed to be ambidextrous. The tests were given to individuals pertaining to the subject area of design and trained in visual communications. None of the subjects involved had been previously introduced to synchronicity issues.

At the end of the test, some information about the subjects' prior experience was collected. Specifically, it was found that the majority of testers (85%) had experience related to the study of music and almost all (90%) had no experience related to wearing wearable devices using vibrotactile feedback. Responding to how they perceived vibratory feedback on a Likert scale of 1 to 5 (1 pleasant, 2 acceptable, 3 mildly irritating, 4 irritating, 5 unbearable) the testers averaged a value of 1.9.
The tests were conducted in a quiet environment with no moving visual stimuli in the testers' field of view. Before the test, subjects filled out an anonymous form with some data about themselves -gender, age, dominant hand-. With the aim of having more involvement in the experience, each tester was told that they would receive a small gift (chocolate bar) at the end of the experiment.

The subjects involved were made to sit at a table on which was a hand control with two buttons (Fig. 1), one on the right and one on the left. At 1.5 meters in front of the subject, a large screen was placed for the testers to look at during the test. Before the tests began, subjects were made to wear two wristbands, one on each wrist, with a small vibrator on the inside of the wrist.

The system was implemented using an Arduino Nano 33 BLE Sense board and the Processing 4 programming language. The decision to use Arduino and Processing was motivated primarily by the flexibility and accessibility that these platforms offer for interfacing with physical sensors and actuators. The visual experience was designed with modularity and flexibility so that it can be adapted and used for further testing and allows the choice of shape, speed, direction of perceptual input, intensity of the vibratory stimulus, and phase duration.

The software allows signals to be sent to the Arduino board via serial to synchronously activate the connected vibro-motors. In addition, the system allows the physical button choices of the testers to be read and the milliseconds used to be recorded (we have indicated 100 milliseconds in the choice as a “false start”).

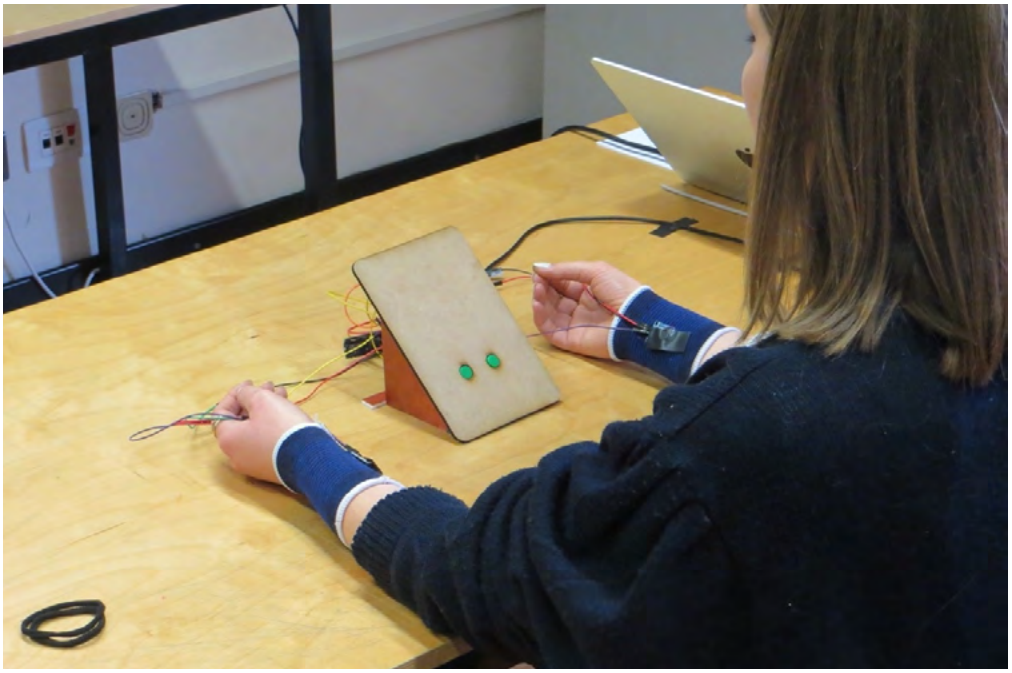

Figure 1. Detail of the prototype.

The objective of the tests (Fig.2) was to verify the effectiveness of rhythmic cross-modal signals to guide the testers' choice. To do this, the testers wore two wristbands with piezoelectric vibrators sewn into the inside of the wrist. In the first test (Fig.3) the vibrators send an identical and simultaneous rhythmic signal on the two wrists. During the test, subjects are asked to watch a video on which two identical circles are moving with the same animation but at two different rhythms. The rhythm of movement of one of the two circles is in sync with the vibration delivered on the tester's wrists (Fig. 4). The test has a duration of 20 seconds, and before the time runs out, the tester has to choose via a button one of the two circles. A countdown timer was introduced in the center of the screen so that subjects would be aware of the remaining time. The test was repeated twice in sequence for each subject. The second time the position of the circles on the screen was reversed.

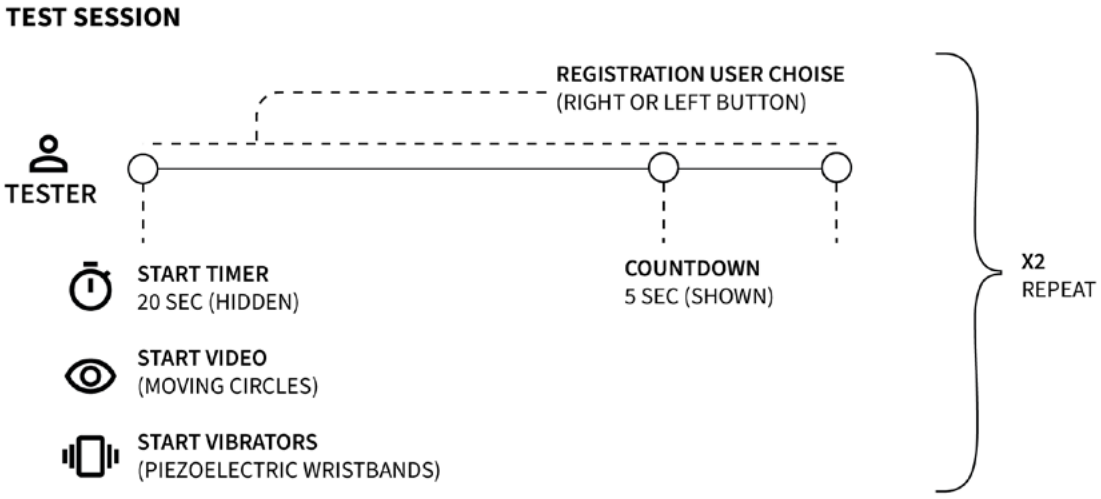

Figure 2. Experiment outline.

Figure 3. Layout of the experiment.

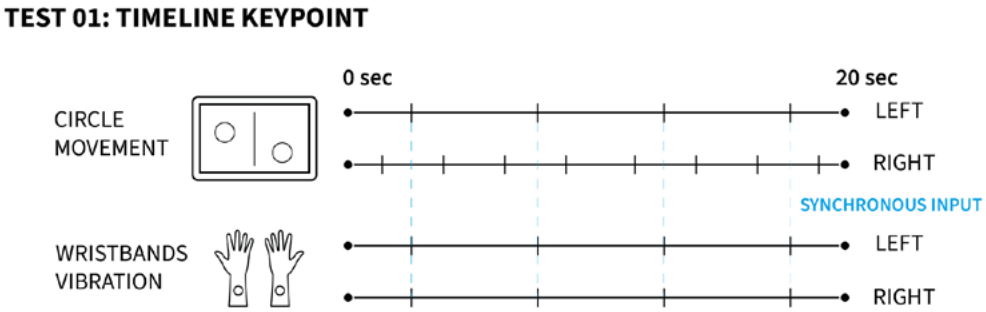

Figure 4. Test 01 process diagram.

The second test (Fig.5) introduces an element of interference in a manner similar to the experiments in the attentional domain that revealed the Simon effect (Simon, 1969). Specifically, the psychologist highlights a conflict between a spatially situated stimulus and a response required of the subject. If the subject is shown an object on the right side of the screen and asked to press a button on the left side, the response will have a slower reaction time than a location coherent with the question asked.

Coherently with the Simon effect in the second test, an asymmetry was introduced in the vibratory feedback on the wrists. The tactile feedback on the right wrist has a longer duration than on the left wrist. This results in a markedly stronger perception of the vibratory stimulus on the right body part. However, the rhythm of both wrists was equal and in synchrony with the circle on the left. The subject was then again asked to choose one of the circles before the 20-second time limit was exhausted.

Thus, two questions were tested with this test: the greater efficacy of choosing a synchronous stimulus over a persistent vibratory stimulus on one side of the body, the possible increase in response time compared with the test without an asymmetrical disturbance element. The second test was also repeated a second time by specularly reversing both the video and vibratory stimuli.

At the end of the exercises, each tester was asked to freely leave a written note about the sensations they felt during the test and the parameters on which they based their choice. Only at the end of this phase were some indications given about the objectives of the test and the research.

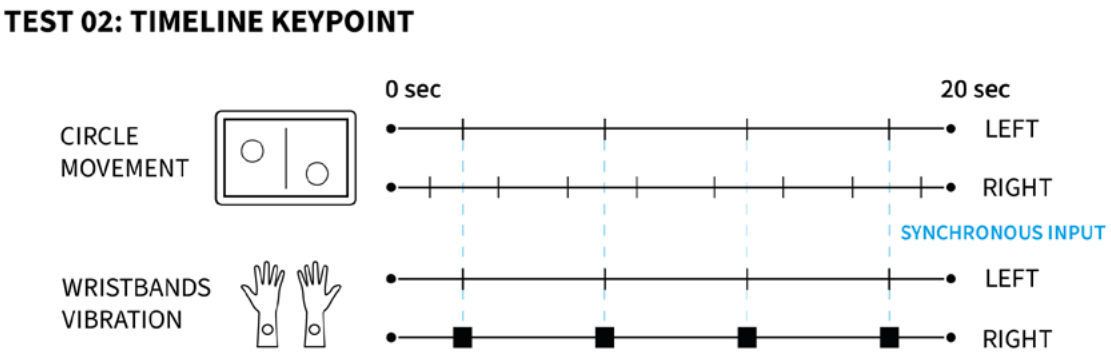

Figure 5. Test 02 process diagram.

5. Data Comparison

In relation to the group of subjects analyzed, the test results do not clearly show dominance in the choice attitudes of the subjects involved. Subjects who gave coherent choices with the cross-modal synchronic rhythmic stimulus investigated were 65.8 percent of the testers versus 34.2 percent. The positive percentage, while greater than the contrary choices, does not indicate a cross-sectional understanding of synchrony. However, it underscores the decoding of the phenomenon of synchrony for a good portion of the subjects.

The table below (Tab. 1) shows the results of the tests conducted. The data analyzed covers 19 subjects; tester No. 16 was cancelled because he reported in the commentary an abnormal functioning of the prototype.

In the Synchronic Choice column, the table reports when the tester's response was coherent with rhythmic synchrony (Y) or when it was different (N). The reaction time for the choice is reported for each question. When the choice was made after the end of the test, the maximum time of 20 seconds of the test was allotted.

5.1 Synchronic Choice

In test No.1A, the majority of testers (14) chose the ball that moved in sync with the rhythm of vibration. This number was significantly reduced in test No.1B where the percentage of testers who gave a positive choice (9) was smaller than those with a negative choice (10).

In test No.2A, the percentage of coherent choices with cross-modal synchronous perception became prevalent again with 14 coherent choices out of 5 inconsistent ones. The result is aligned with test No.2B with 13 positive choices out of 6.

Looking at the choices given by each tester, we can see that only 4 of them gave 100% positive choices, 6 gave 75%, 6 gave 50%, and 2 gave 25%. One subject gave all negative choices.

5.2 Reaction Time

Most of the subjects made their choice before the 20 seconds expired. Out of a total of 75 responses, 21 were given before the middle of the test (10 s) while 46 were given before three quarters of the test (15 s).

Observing the data in a comparative manner of test No. 1A and test No. 1B shows a general increase in reaction time. However, looking only at the data for coherent choices with synchrony, the average reaction time drops from 14.037 s to 12.685 s.

The comparison of reaction times between test No.2A and test No.2B is different. The overall average reaction time rose by almost 4 seconds as that for coherent answers with synchrony rising from 9.857 seconds in test No.2A to 14.467 seconds in test No.2B.

Analyzing the overall averages of the cross-modal coherent answers increased from 13.361 seconds in the first two to 12.162 seconds in the third and fourth exercises.

Table 1. Results of tests. Yes (Y) means a choice potentially based on synchrony, No (N) means the opposite. The Reaction time column indicates the time it takes for the tester to press the choice button (from the start of the test).

6. Discussion

The introduction of test repetition is directed to verify an increase in coherent choices following the experience in the first test. In contrast to the initial assumption, test repetition shows a decay in coherent choices with the perception of a cross-modal synchronous rhythm. These results could indicate how synchrony is quickly encoded by subjects; however, over a longer time, other factors take over in guiding the final choice.

This observation holds true for both tests conducted. While in the former we see the actual decay of coherent choices, in the latter what visibly changes are the increased reaction time of the decision. This could be due to uncertainties the testers had.

Test No. 2 was designed to challenge the perception of synchrony. To do this, an interference factor was introduced. However, the results do not show a deterioration in coherence compared with test No. 1. On the contrary, the increase in vibratory sensation, although asymmetrically with respect to the body, led testers to choose a coherent choice with synchrony. This was also the case in the repetition of test No. 2. The diagram below (Fig. 6) compares the percentage for each tester of coherent choices in rhythm with the observations they wrote on a sheet of paper at the end of the two tests. The observations were read, and each was assigned the prevailing perception described by the tester (1 subject declared nothing, 2 subjects declared confusion, some testers placed greater importance on the sense of sight, and a greater number reported placing great importance on vibration). Finally, many testers indicated that they felt a shared rhythm or synchrony between the visual and tactile sensations even though this did not always then match the choices.

The graph is interesting because it highlights how testers were aware of the phenomenon of synchrony and tried to guide their choices based on this. In the testers' declarations, touch had a greater incidence than the sense of sight.

The data analyzed support further development of cross-media synchrony and application in multiple application areas. One example is the attention relationship between visitors and information content in museum and exhibit. Another area is safety in the workplace through increased awareness of body-contact information. Finally, the rehabilitation field could also accommodate further development of the topic.

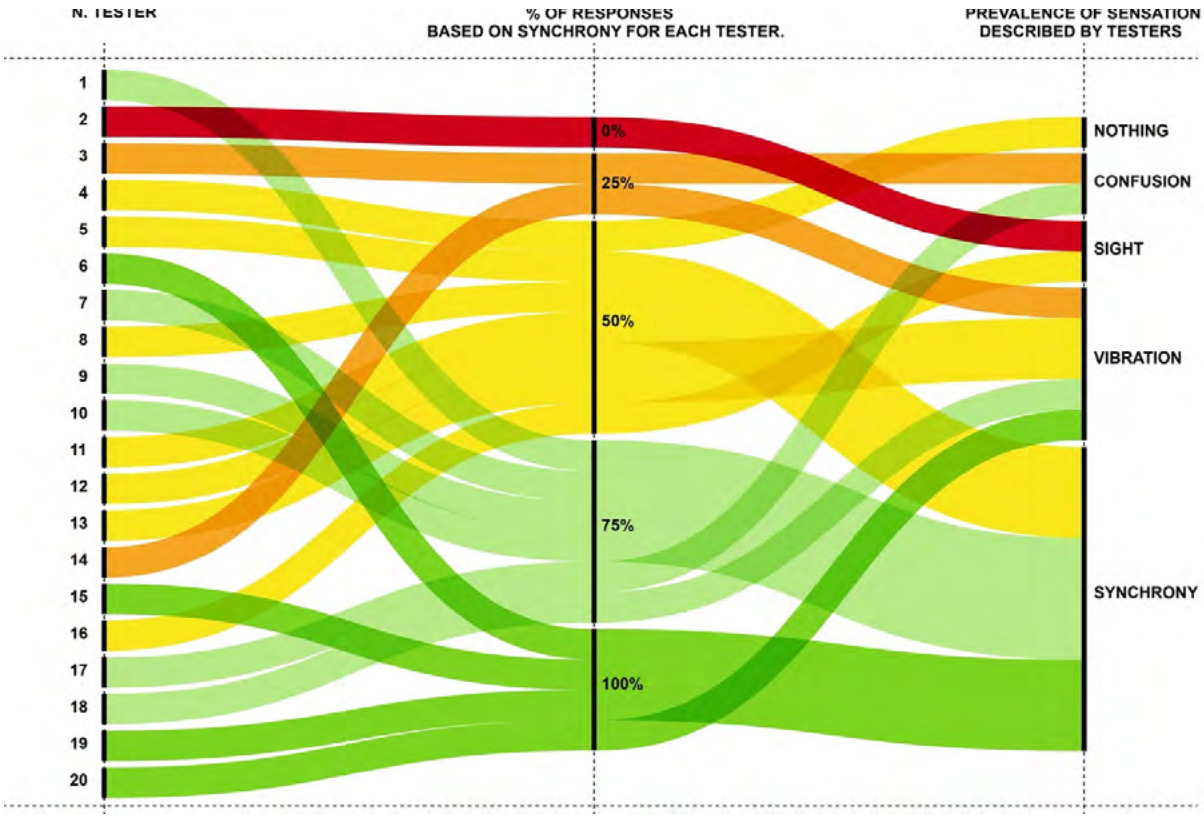

Figure 6. Alluvial diagram of research results. The diagram highlights the relationship between the percentage of responses consistent with the synchronic stimuli and the sensation communicated by the subjects after the two tests.

7. Conclusion

Public and private spaces are increasingly integrated with pervasive digital technologies and invisible human-machine interfaces. Therefore, in the field of interaction design, it is necessary to introduce design elements that support attentional processes capable of integrating naturally with human senses.
The characteristics of touch, such as noninvasiveness and proximity, grant haptic technologies a high degree of mimicry and personalization of information while respecting the user's privacy. This makes them useful for handling various types of messages between the body and the interactive systems around it.
One can imagine a personal scenario in which notifications arrive silently to only one user compared to other people in the same room. For example, the alarm clock in the morning vibrating on a wearable could wake only one person from a couple living together, or messages received within a crowded study room. These scenarios are already widespread in the haptic device landscape but anticipate broader design scenarios yet to be studied in the field.

Among the many components that come into play in the modulation of haptic technologies used in human-machine languages, rhythm is a determining factor in consciously and unconsciously suggesting responses in people's behavior. Synchrony is a rhythmic phenomenon that the body perceives with its senses, and there is evidence that the human body can associate multimodal sensations, that is, from different sensory channels. Rhythm has cross-sensory communicative capabilities (cross-mediality) and can relate multiple senses simultaneously (cross-modality).

The possibility of advanced integration of designs that work on haptic stimuli in the field of immersive and at the time expository technologies becomes central to the design of experiences regardless of whether they are physical or virtual. The complexity dictated by the addition of media that is conveyed through haptic vibration requires a long phase of design experimentation. The evaluation proposed in this contribution demonstrates that this direction is viable at both the conceptualization and developmental levels.

7.1 Limitations and Future Developments

The experimental tests conducted show that cross-modal rhythmic and synchronic stimulation has a good ability to guide users' choices. However, some boundary factors emerge within this study that need further analysis to check for possible interferences in the evaluation of the results. For example, additional factors come into play in determining a choice preference that may lead subjects to act differently.

Following the experiments, some evaluations emerged in the data analysis regarding the subjects' prior experience with respect to rhythmic perception. Previous musical experiences by the testers may have contributed in rhythm perception. Lack of familiarity in the use of smartwatches by some testers and lack of familiarity with vibration sensations in the wrists may also have influenced the responses. A larger sample that takes these factors into account could be the subject of a subsequent exploratory investigation in which these first two experimental tests could be supplemented by additional items for evaluation.
To improve the quality of stimuli sent to the body, wireless haptic bracelets will be used in future experiments. The use of wearables will allow testers to assume a more comfortable and less constrained position. In addition, the wearables will also allow some tests to be conducted with the body moving within a controlled space.

The experimentation lays the groundwork for further research around cross-modal synchrony as an element in engaging people and supporting decision-making and attention processes in digital information-dense environments. Subjects' response to synchrony effects underscores the opportunity for applications designed to increase the connection between the body and the interface in immersive experiences.

About the Authors:

Giorgio Dall'Osso is a researcher in design at the University of the Republic of San Marino. His research focuses on the relationship between bodies, spaces and technologies. His research interests also focus on basic design and behavior design.

Michele Zannoni is an associate Professor in Industrial Design at the Università di Bologna. His published articles and books explore the intersection of interaction processes and visual and product design. His scientific research is concerned about digital and physical products and the evolution of the user interface.

Luca Barbieri is a technical tutor of the DA Makers LAB at the Department of Architecture in Bologna and collaborates with Advanced Design Unit on research projects in Interaction design, gaming and interactivity for museums.

Acknowledgements: The introduction chapter (1) is by Zannoni and Dall'Osso. Chapters 2 and 3, on the relationship between haptic stimuli and the body are by Dall'Osso. The experimental test (4) is by Barbieri, Zannoni and Dall'Osso. Data analysis, discussion are by Zannoni and Dall'Osso. Conclusions are by all authors.

ABSTRACT | The paper investigates Extended Reality (XR) advanced representation application paradigms in collaborative product design sessions. The research stems from the pressing need for innovative solutions to address the challenges posed by the global pandemic, particularly the necessity for collaborative telepresence due to enforced social distancing. In this scenario, XR and similar technologies as Virtual Reality (VR) have opened new design possibilities.

Therefore, the primary objective of the research is to investigate how XR technology, as an advanced representation system, can effectively contribute to industrial design, particularly in its collaborative phases. This study examines the technology landscape of XR in terms of challenges encountered by tools on a practical basis for industrial design.

This research addresses a central question: Can XR enhance “triggered” design practices by facilitating collaboration when sharing an unfeasible physical space?

The methodology includes a case study analysis conducted as exploratory studies, blue-sky research, and a thorough examination of academic and commercial XR applications. Each case study is categorised based on pertinent variables, focusing on collaboration and technological accessibility criteria. The outcomes offer a map that aligns case studies within the design process.

The map summarises the main results of the research. While not claiming to be exhaustive, its purpose is to provide an assessment framework and stimulate reflection on incorporating case studies into the design process. The map includes information on the strengths and weaknesses of current technologies and available resources serving as inspiration for future implementations.

1. Introduction

1.1 Background and Context

This research intends to explore and verify the possibilities of using eXtended Reality (XR) tools in collaborative design sessions. The study is based on a pressing need for innovative solutions to deal with global pandemic challenges, in particular, the necessity of collaborative telepresence due to enforced social distancing where Virtual Reality (VR) and similar technologies have opened new design possibilities (Strand, 2020; Vi et al., 2019). This requirement is thought to tackle challenges arising from the pandemic while generating lasting possibilities, such as improving remote collaboration and lessening the environmental impact of travel fields. Even beyond the immediate pandemic emergency, exploring this research area remains opportune, as it addresses workplace flexibility and enables design teams to simulate an in-person experience regardless of their location (Li et al., 2023).

Furthermore, there is a growing focus on exploring the collaborative aspect, particularly as co-design gains significance in addressing complex technological, social, and educational situations. An alternative approach becomes essential when no person has all the knowledge and skills to understand and solve these complexities (Zamenopoulos & Alexiou, 2018). In this paper, the collaborative session is to be taken as when stakeholders with different skills and capabilities work together towards a common goal to solve the design challenge, particularly during brainstorming sessions to define the brief, review sessions during project development, final refinement and testing and product presentation.

The future of XR technologies is envisioned as a collaborative and distributed infrastructure. As anticipated, users and specialists will interact and organise activities on a global scale through mediated environments (Nguyen & Bednarz, 2020). XR technologies integrated into collaborative user interfaces improve communication, facilitating seamless functional and cognitive workflows among users (Billinghurst & Kato, 1999) and augmenting the sense of co-presence. Schroeder (2002) summarised that co-presence refers to "*being there together*" and engaging with other users concurrently.

The Research XR_CODESTO (eXtended Reality Collaborative Design Tools) aims to explore and define new ways advanced representation systems, such as XR technology, can be effectively utilised in industrial design, mainly in its work-sharing phases. Given the evolution of technologies, this exploratory research, which still needs to be completed, aims to address the challenges XR technology faces in finding practical applications within the industrial design field. This would help designers and stakeholders overcome geographical limitations, achieve working continuity, and enhance the overall design experience (Ratcliffe et al., 2021). Additionally, the research aimed to contribute towards bridging the gap in knowledge and understanding of XR technology by providing insights into its practical implementation and benefits within the industrial design field and its related didactics.

Furthermore, the research aimed to contribute to the dissemination of XR technology and identify future research needs relating to pedagogical integration, digital skills, and digital infrastructure. Overall, the research aimed to explore and demonstrate the potential of XR technology in industrial design, address challenges posed by globalisation crises, establish XR as a valuable and widely used tool in the industrial design process, and contribute to the standardisation and future development of XR technology.
The subsequent paragraph aims to provide a concise theoretical overview of the primary subjects investigated in the research: Extended Reality and Collaborative Design session.

1.2 Extended Reality

Extended Reality (XR) is an overarching term that encompasses a broad spectrum of immersive technologies, including Virtual Reality (VR), Augmented Reality (AR), and Mixed Reality (MR). Using the Reality-Virtuality Continuum is imperative to clarify the Extended Reality concept, engaging with the

framework posited by Milgram et al. (1994). The continuum concept is a critical analytical tool, facilitating a nuanced comprehension of AR, MR, and VR while elucidating the intricate interrelations that link these technologies.

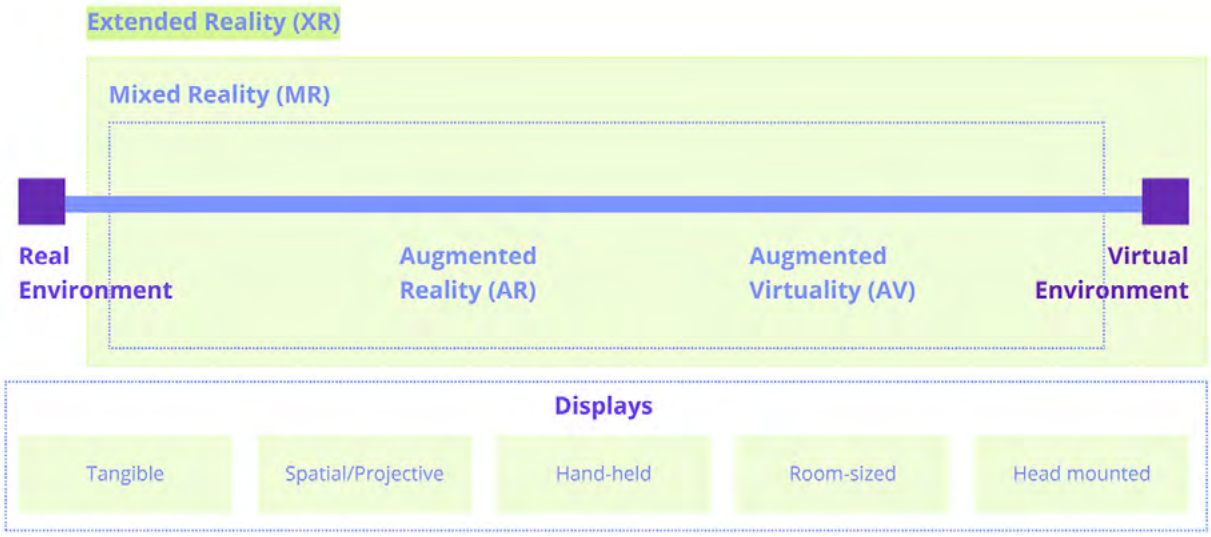

Figure 1. Diagram describing Milgram et al. (1994) Reality-Virtuality Continuum and adding the definition of the set of XR displays (Milgram & Kishino, 1994).

The Reality-Virtuality Continuum is articulated through two polar extremes: on one end, the not-changed real-world environment, and on the opposite end, a wholly virtual environment representative of VR. The intermediate space, which diverges from these extremes, is categorically delineated as Mixed Reality (Speicher et al., 2019). MR manifests in many forms within this intermediate domain, each uniquely characterised by varying degrees of immersion and the interplay between virtual elements and the natural environment. This diverse categorisation encompasses technologies such as Augmented Reality - wherein a predominantly real-world context is enhanced with virtual elements; Augmented Virtuality - a scenario that predominantly exists within a virtual realm yet incorporates elements of the real world to varying extents; Mediated Reality (Mann et al., 2018) (encompassing technologies like XY-R, designed to alter the perception of reality for specific purposes, such as augmenting the colour perception for individuals with colour blindness, thereby affording them a more accurate representation of their environment); and Diminished Reality (Cheng et al., 2022), which involves the technological elimination or reduction of real-world elements from the user's perception.

The delineation of XR has evolved in contemporary years, now being conceptualised as an amalgamation of Virtual Reality and all technologies that fall within the ambit of Mixed Reality. This broadened definition underscores XR's fluidity and expansive nature as a field, highlighting its capacity to integrate and synergise various immersive experiences. By encompassing a wide array of technologies that straddle the continuum from the entirely real to the fully virtual, Extended Reality stands at the forefront of technological innovation, pushing the boundaries of how digital and physical realities can converge to create novel and enriching experiences.

1.3 Collaboration in the Design Session

For this research, collaborative sessions are strategically integrated throughout the phases of the product design process, exhibiting variability in their type and frequency, contingent upon the intrinsic characteristics of the design process, its inherent complexity, and the phase of implementation. Individuals are engaged, assuming various roles, and may participate across different design project levels and stages. In line with the model of the Double Diamond (DD) (Design Council, 2005; Kochanowska et al., 2022) proposed by the Design Thinking approach, engagement in design starts with the "discovery" of nascent needs or opportunities within a specific context, proceeds with the "definition" of particular interest or

challenge to be addressed, the "development" of viable ideas capable of addressing such situations, and culminates in the "delivery" of a (prototyped) solution to a distinct problem or opportunity.

This iterative process, characteristically non-linear and frequently recursive, shows varied ways of interaction influenced by the participants involved and the degree of detail attained. Aligning the DD model with collaborative practices (Figure 2), we can see that at the beginning, collaborative sessions mainly focus on defining or analysing the project brief, using low-tech tools to facilitate meetings, image exchange and brainstorming activities. These meetings serve to outline the inspirations and define the project constraints. During the intermediary phases, as the concept idea advances towards materialisation, the nature of collaborative sessions switches to design reviews.

This phase aims to advance towards a more refined articulation of the project, demanding the involvement of a broader spectrum of stakeholders and ensuring that the fidelity of representations incrementally aligns more closely with reality.

The final phases are dedicated to prototyping and testing. Herein, collaborative sessions are convened with a focus on the iterative refinement of the project, aiming to rectify any discrepancies before transitioning towards actual production. In the last phase, the testing is better done with the final users to verify whether the project result meets their needs, and the collaboration becomes even more complex. To conclude, the crucial role of collaboration at every stage is facilitating a holistic and iterative design process that optimises outcomes and enhances the feasibility of the final product (El-Jarn & Southern, 2020).

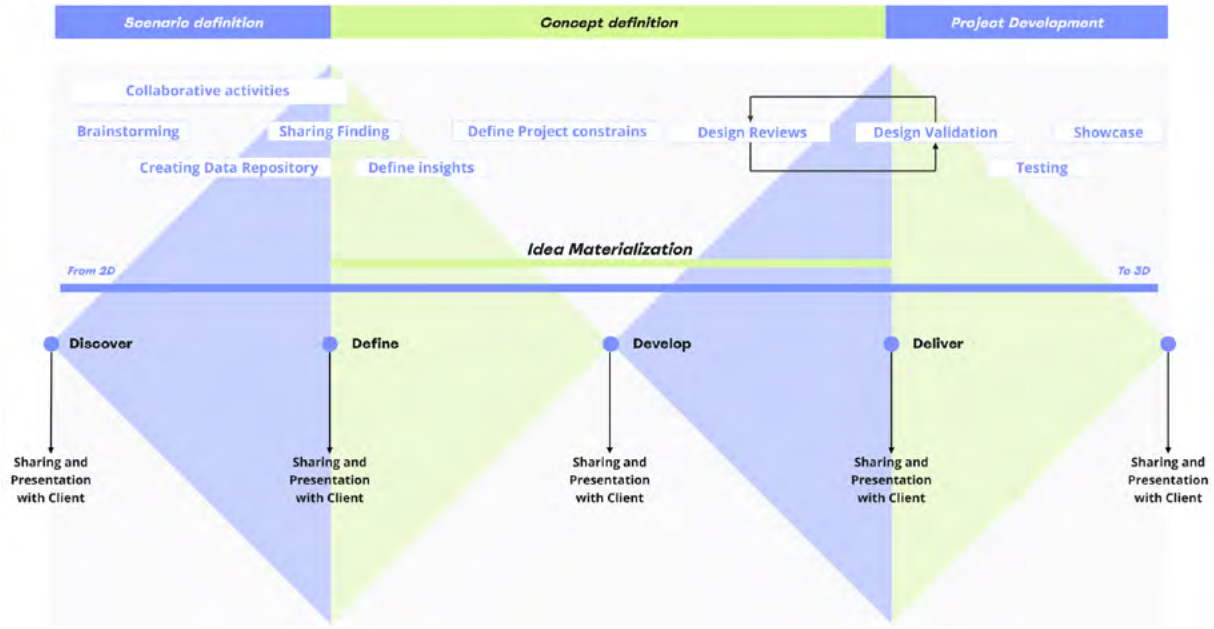

Figure 2. Collaborative session applied to the DD model, authors reinterpretation.

1.4 Representation Techniques

The methodologies and techniques employed in articulating ideas and concepts throughout the various phases of the design process are tailored to meet the unique requirements of each distinct phase within the process (Novoa Munoz et al., 2022). In the incipient stages of a project, representation is predominantly delegated to techniques of a fundamentally two-dimensional nature. This encompasses freehand sketches, which facilitate the exploration of initial ideas alongside reference images and mood boards. These tools are instrumental in delineating the project's conceptual framework and aesthetic ethos, providing a foundational visual vocabulary upon which subsequent development is predicated (Purcell & Gero, 1998).

As the design process advances, there is an evolution in the representation methods, which progressively embrace complexity since it is moving towards a three-dimensional perspective. This transition is exemplified by adopting a study maquette, which helps stimulate a tangible understanding of spatial dynamics and shape or provides volumetric three-dimensional constructs and a more realistic representation of the project. These instruments are pivotal, not merely for enhancing the visualisation of spatial relations and integrating elements but also for facilitating a simulation of the project with its context (Bellini, 2019).

In the final stages of the design process, the focus shifts towards generating lifelike models. These representations, often the product of modelling and rendering technologies, enable a precise visualisation of the project, meticulously accounting for variables such as lighting, materiality, and construction specifics. Thus, they accurately portray the anticipated outcome, significantly augmenting the dialogue among designers, clients, and stakeholders. This, in turn, allows for a comprehensive evaluation of the project's aesthetic and functional alternatives before its materialisation, ensuring a confluence of vision and execution that is both coherent and anticipatory of the project's intended impact (Kuys et al., 2023).

Figure 3. Methods and techniques of representation applied to the DD model, authors reinterpretation.

2. Methodology

Starting from a framework defined with the preliminary literature review, a qualitative research method was chosen for this research to explore the topic better. Qualitative research methodologies, encompassing case studies and best practices, are applied to explore the research question. Employing a mapping process, the research assesses diverse XR tools applied in design processes, specifically emphasising those supportive of co-design sessions.

This phase has been researched on state-of-the-art technology, emerging market trends and reports, and the implementations already in progress identified as opportunities. In this step, the team explores XR's possibilities by identifying interesting case studies and best practices.

The research process unfolds through four principal phases explored in the following paragraphs.

Table 1. Summary of activities, results achieved, and people involved.

Phase	People	Role	Type of activities	Outputs
Preliminary Exploratory	4	1 Research Fellow in Representation 2 Research Fellow in Design 1 PhD Student in Design	Analysis of the latest advancements in technology. Identifying and interpreting emerging trends within the marketplace.	**Collecting Data**
Collaborative Co-design Workshop	7	1 Research Fellow in Representation 2 Research Fellow in Design 1 PhD Student in Design 3 Students of MSc in Design	Understand the previously selected case studies, examine them, and define evaluation criteria.	**Case Studies Selection** **Case study "cards"**
Final Synthesis	5	1 Research Fellow in Representation 2 Research Fellow in Design 1 PhD Student in Design 1 Students of MSc in Design	Distil the information derived from the case study analysis into clusters, and to pinpoint the various connections within the design process.	**Case Studies Mapping**
Didactical Application	95	60 students of BSc in Product Design 15 students of Specializing Master TAD 20 students of an Elective course for MSc in engineering and design	Dissemination of the research findings and use as a didactical tool aimed to equip future professionals with the knowledge and skills to leverage XR technologies.	**Implementing tools for education**

2.1 Preliminary Exploratory Phase

In the Preliminary Exploratory Phase of the research, the initial objective was to examine and understand the contemporary XR technological landscape. This included an analysis of the latest advancements in technology, identifying and interpreting emerging trends within the marketplace, and recognising existing implementations that were deemed to hold potential for opportunity. This phase serves as a foundation for further investigation, aimed at collecting data and then analysing and synthesising it during the second phase.

At this stage, the team started with an exploratory literature review, examining the fundamental aspects of XR reality, with the methodology developed by Milgram et al. (1994) as a guide for the work. The focus was identifying research addressing design principles and illustrating practical applications through case studies. Simultaneously, the team engaged in an online XR MOOC (Nebeling, 2020) introductory course to understand XR technologies necessary for subsequent analytical phases. A trend analysis was also conducted using the Hype Cycle for Emerging Technologies, referencing reports from 2017 to 2022 (Gartner, 2017; 2018; 2019; 2020; 2021; 2022). The team selected emerging technologies relevant to their area of focus, using these trends to inform their commercial analysis. This involved thorough desk research to identify device systems and tools suitable for integration into the design process.

The output of this initial investigative stage was selecting a collection of case studies. Each chosen case study was explicitly aligned with the research goal that had been previously established. The goal serves as a filter allowing a focused examination of the technological landscape, choosing a case study directly relevant to the research.

2.2 Collaborative Co-design Workshop

The preliminary exploration phase laid the groundwork for an in-depth exploration, setting the stage for the subsequent phases of the research. A collaborative Co-design workshop followed the first phase. During the Collaborative Co-design Workshop, the primary goal was to understand the previously selected case studies, examine them, and define evaluation criteria. This phase was characterised by engagement, where participants were tasked with critically examining and classifying each case study.

The output of this workshop was case study cards that serve as a visual synthesis of each case study and related parameters. Despite the inherent diversity, these cards served as a pivotal output of this phase, offering a more precise and structured understanding of each case study.

Furthermore, this phase establishes the conceptual framework that allows us to bridge the theoretical underpinnings of XR with the design process.

2.3 Final Synthesis and Future Application

In the concluding phase of the research, the Final Synthesis and Future Applications, the effort was to amalgamate the insights into a coherent synthesis. The objective here was twofold: firstly, to distil the information derived from the case study analysis into clusters, and secondly, to pinpoint the various connections within the design process and understand where the technologies under consideration could be most effectively applied. Identifying these clusters was foundational to defining a conceptual framework for future explorations.

Equally important was the identification of specific steps within the design process where the technologies could be seamlessly integrated. This required a thorough understanding of the design process, including its various phases, requirements, and outcomes. The goal was to ensure that technology integration was not additive but transformative, enhancing the design process in meaningful and sustainable ways. The research aimed to provide actionable insights that could be directly applied to design challenges.
The output of this final stage was a comprehensive synthesis that mapped the case studies within the identified clusters and delineated the potential pathways for the future application of the technologies.

2.4 Didactical Application

This phase primarily focused on disseminating the research findings and fostering the professional adoption of XR technologies. This stage was essential in translating the theoretical insights and analytical conclusions drawn from the research into actionable knowledge and practices that could be readily applied within professional and educational settings. A strategy was employed to integrate the research outcomes into professional development and academic instruction to achieve this. The research serves as a groundwork to inspire various educational initiatives designed to cater to a diverse audience, ranging from industry professionals to students within the higher education sector.

The research findings were integrated into professional master's programmes, specifically within the automotive sector. Allowing the students to select among the case studies the ones that better fit their needs during the design process. Moreover, the conceptual framework will be used as an evolving tool to understand the technologies on the market and open up possible XR implementations and experiments. In this way, the integration aimed to equip future professionals with the knowledge and skills to leverage XR technologies to advance automotive design.

Furthermore, an elective course for master's degrees was also developed. This course was designed to foster interdisciplinary collaboration and innovation, enabling students from diverse academic backgrounds to explore the synergies between technological advancements and design principles through the lens of XR technologies. Additionally, the conceptualisation of a virtual laboratory represented a significant advancement in the educational application of the research findings.

Through these diverse educational initiatives, the Didactical Application phase sought to disseminate research findings and inspire and facilitate the widespread adoption of XR technologies. By embedding these technologies within the curricula of professional and academic programmes, the phase aimed to cultivate a new generation of professionals and scholars well-versed in applying XR technologies, thereby contributing to advancing the field and realising its full potential across various domains.

3. Collaborative XR Case Studies

3.1 Case Studies Selection

The case study method has been chosen because it is beneficial for understanding and generating explanations for complex phenomena (Anderson, 1993; Yin, 2009). Also, it provides the opportunity to investigate every case/project in depth. Therefore, the case study method could analyse the scenario through different design paradigms.

The first step to starting a case study is to draw the boundaries of the cases. Yin (2009) stated that more significant heterogeneity among cases could increase generalisations. Instead, the homogeneity might support internal validity.

According to these assumptions, the selected cases were chosen among XR devices/systems/tools that could be used in collaborative design processes. Then, these cases were examined regarding their availability and readiness to the market, their collaborative qualities, accessibility, and cross-integration between different platforms. Defined indicators have been applied to select and filter the first results according to the scope of this research, such as:

- Year of publication and date when the case study was conducted. Due to the growth rate of the rapid technological improvement of XR instruments and the depreciation of older ones, it must be considered that this type of technology undergoes a very rapid obelise. The release date is an essential indicator when looking at case studies;
- Field of application. As stated above, the research is focused on design-related industries that require the almost simultaneous use of XR tools among several stakeholders remotely, attending the session in the same physical space or a combination of them. For this reason, most research released in our selected timeframe regarding medical, military, and other external fields in which the interaction described is only human to machine or vice versa has been avoided;
- The level of interaction and collaboration such tools could offer to end users. It underscores the emphasis on collaborative aspects within the solutions being explored in the research. More interaction among more than two users is seen as having increased significance in the study context. Tools that, per se, were not designed for collaboration were not excluded because, when put into the system, they could still be of interest to the study.

The case collection and selection process in this research involved two distinct phases. Initially, cases were selected based on preliminary criteria and later refined during a co-design session. Consequently, the initial selection underwent a secondary review. During the first phase, 20 case studies were gathered via web-scraping by predetermined criteria. A subsequent screening process was conducted to exclude cases based on relevance to design collaboration, the quality of technology representation, and redundancy. When faced with similar cases, only the one best suited to the research requirements was retained. This approach resulted in the exclusion of 7 case studies.

Here is the list and a brief description of the selected case studies after the selection phase.

1. Gravity Sketch with LandingPad (Gravity Sketch, 2021): 3D design platform for cross-disciplinary teams to create and collaborate in virtual reality;
2. Spatial IO (Meta Quest, 2020): Customizable virtual space for meetups, NFT art exhibitions, and live events;
3. Campfire (https://campfire3d.com): A system consists of a headset and software for design collaboration in a remote world;
4. XR with Unity3D (https://www.khronos.org/openxr/): Cross-platform for designing and developing AR/VR/XR Experience;

5. 3DFrames for Webex (Grandis, 2022): A metaverse app for Webex. It helps teams meet virtually to conceptualise plans and present products;
6. Spark project (O'Hare et al., 2020): A tool that applies augmented reality in co-creative design sessions by projecting texture on 3D objects;
7. CAVE (Virtual Environments Group, 2013): A cubic room with projection screens aims to create a virtual environment. In which users wear eyewear to interact with visual stimuli;
8. Realtime VR projection(https://www.nuformer.com): Real-time projection on the environment's external surfaces while the user performs in virtual reality;
9. Tesla Suite & Tesla Glove (https://teslasuit.io): A full-body haptic feedback system provides the user with haptic feedback. Also, it captures the user's motion and biometrical data;
10. Sense glove (https://www.senseglove.com): Force-feedback glove that can be integrated with the VR system, allowing the user to gain a sensorial experience from the virtual environment;
11. Logitech VR Ink Stylus (https://www.logitech.com/en-eu/promo/vr-ink.html): VR stylus allows designers to create geometries in two-dimensional physical surfaces or three-dimensional room-scale space;
12. Touchable hologram (Baraiuk, 2014): System that uses sound waves to project "haptic holograms" into mid-air –letting the user touch 3D virtual objects with his bare hands;
13. InterHaptics (https://www.interhaptics.com): 3D design software for building interaction 'design hand tracking' and composing haptics for AR/VR applications for cross-disciplinary teams to create and collaborate in virtual reality.

3.2 Case Studies "Cards"

Upon selecting the case studies, the co-design workshop was convened to establish indicators that encapsulate the characteristics inherent to each case. This workshop was planned as a co-design activity to foster exhaustive comprehension among six participants. It saw the research team's collaboration with two young designers and was methodically organised, drawing upon insights from preceding research.

The activities conducted within this workshop were directly inspired by the selected case studies, engaging participants in a collective effort to review and refine the evaluation parameters.
The workshop served as a debate for exchanging perspectives and facilitating open discussions. The discourse that ensued was instrumental in refining the evaluation criteria for the case studies, culminating in the creation of evaluative cards summarising each case study's findings (Figure 4). These cards function as a comparative matrix, enabling a consistent comparison of case studies through the visual representation of parameters, enhancing clarity and comprehension.

This categorisation encompassed the following parameters:

- Device/System/Tool: This dimension delineates whether the case study is classified as a device (a tangible instrument such as a viewer), a system (a complex amalgamation of infrastructure, device, and software), or a tool (software developed to facilitate the use of XR);
- Academic/Industry R&D: This categorises the case studies based on their origin, differentiating between those emerging from academic research projects and those developed within industrial research and development contexts;
- Stand-alone/Add-on: This classifies the case studies based on their operational independence or requirement to use other devices, systems, or tools.
- Black/White box: This distinction is related to the potential for customisation the case study offers, primarily regarding software.

After this preliminary classification, the evaluative cards were enriched, adding other evaluation criteria. In this case, a value from 1 to 5 was given:

- Specific Equipment Required: This criterion assesses the extent of specific equipment necessity;

- Ready to Market: This evaluates the market readiness of the case study, awarding the highest score to those already available on the market;
- Collaborative: This measures the degree to which the case study facilitates collaborative efforts;
- Accessibility: This assesses the accessibility of the case study in terms of the requisite skills for users;
- Cross Integration: This evaluates how the case study can be integrated with other Devices, Systems, or Tools.

These evaluative metrics and classifications provided a structured approach to understanding the diverse case studies, facilitating a systematic analysis informing the subsequent research and application phases.

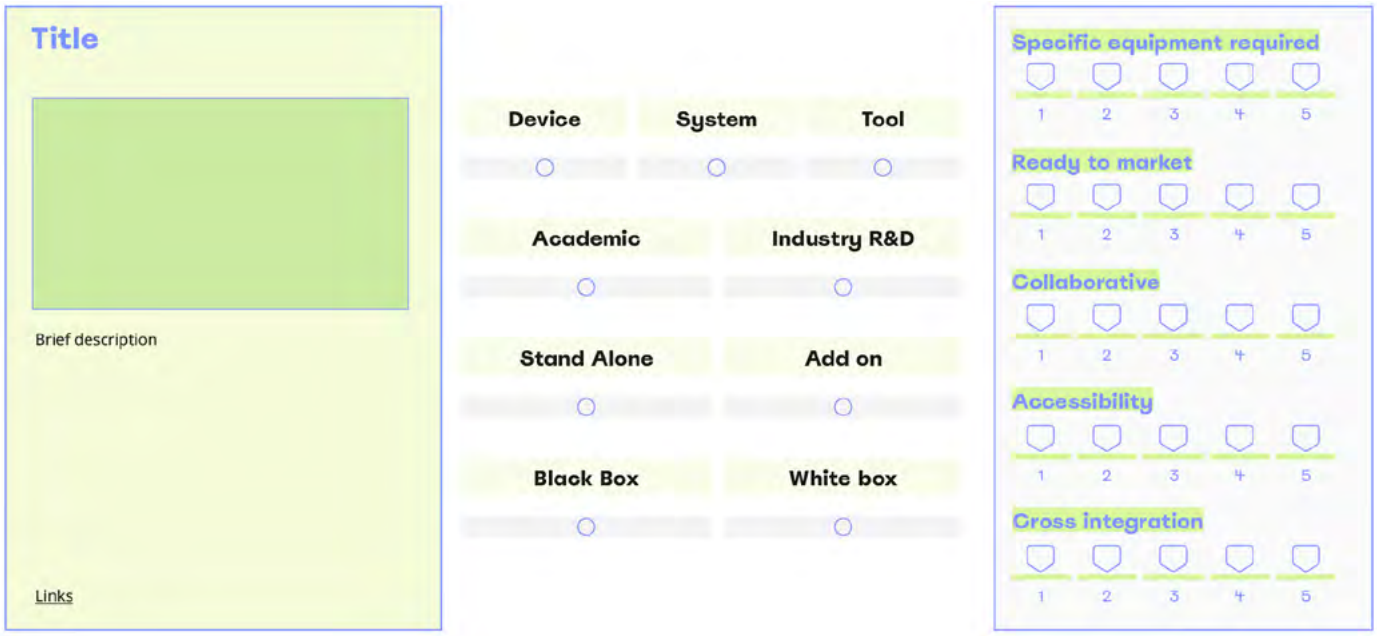

Figure 4. The case study evaluation grid.

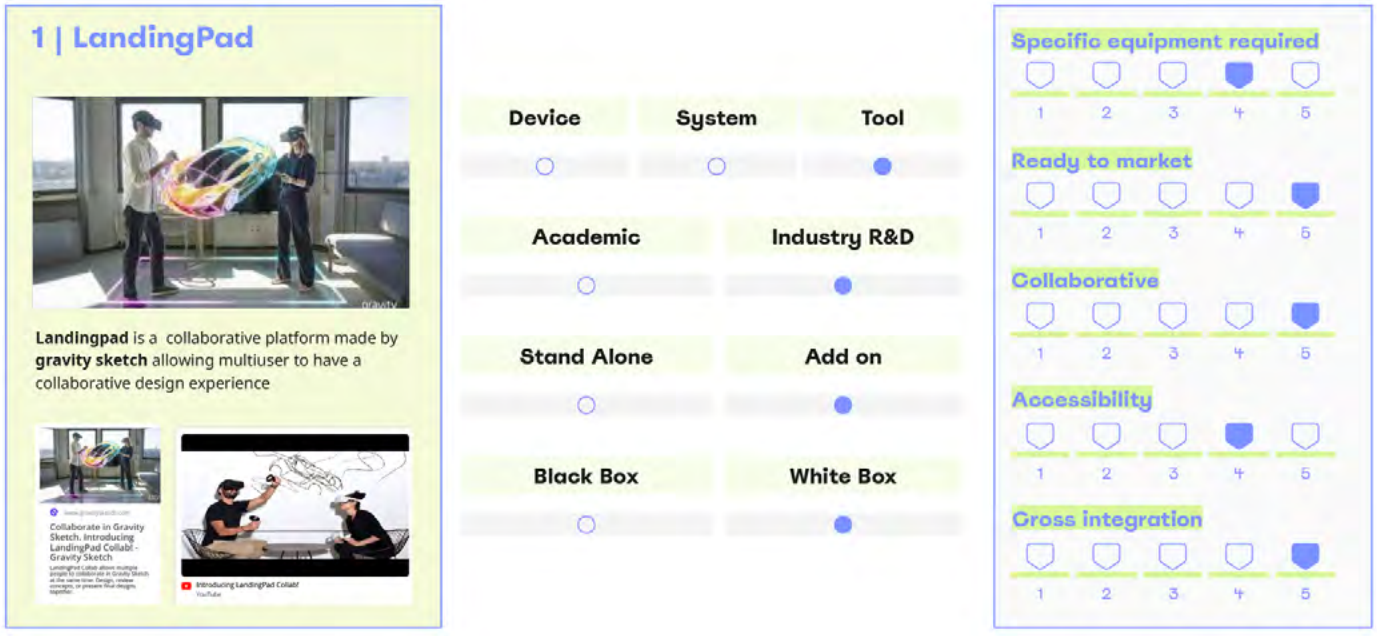

Figure 5. The case study evaluation grid, applied to a case study.

3.3 Case Studies Mapping

After this refinement and categorisation, the research established an additional evaluative stratum. This phase was characterised by creating a conceptual framework (Figure 5) that signifies an integration of two foundational models: the Double Diamond model, which delineates the structured phases of the design process, and the Milgram continuum, which represents the spectrum of reality-virtuality integration. The primary ambition behind this framework was to merge the Double Diamond model with the reality-virtuality continuum proposed by Milgram to combine the two concepts under inquiry. This phase produces a map that facilitates the strategic positioning of case studies concerning their congruence with the distinct phases of the design process, as well as their placement within the reality-virtuality spectrum. Consequently, the horizontal axis of the map delineates the alignment of case studies with the Double Diamond model's mapping of the design process, considering that a single case study may bear relevance to multiple stages of design, so it cannot have a single place but more than one. Meanwhile, the vertical axis categorises case studies according to their positioning within the Milgram continuum, from a fully real environment (bottom) to a fully virtual environment (top).

This map serves as a visual summarisation of the principal findings of the research. While it does not claim to be an exhaustive representation, especially considering the rapid evolution with which these technologies advance, its construction is intended to offer a structured framework for subsequent evaluation. Its objective is to catalyse reflection on the potential integration of the examined case studies into the design process. It provides a novel lens to consider the intersection of design methodology and the reality-virtuality continuum. Additionally, the map provides insights into the strengths and weaknesses of current technologies, thereby serving as a source of inspiration for future implementations. This evaluative tool facilitates a deeper understanding of the landscape of technology application within design, encouraging a vision of how emerging technologies might be harnessed to enrich and expand the boundaries of design practice.

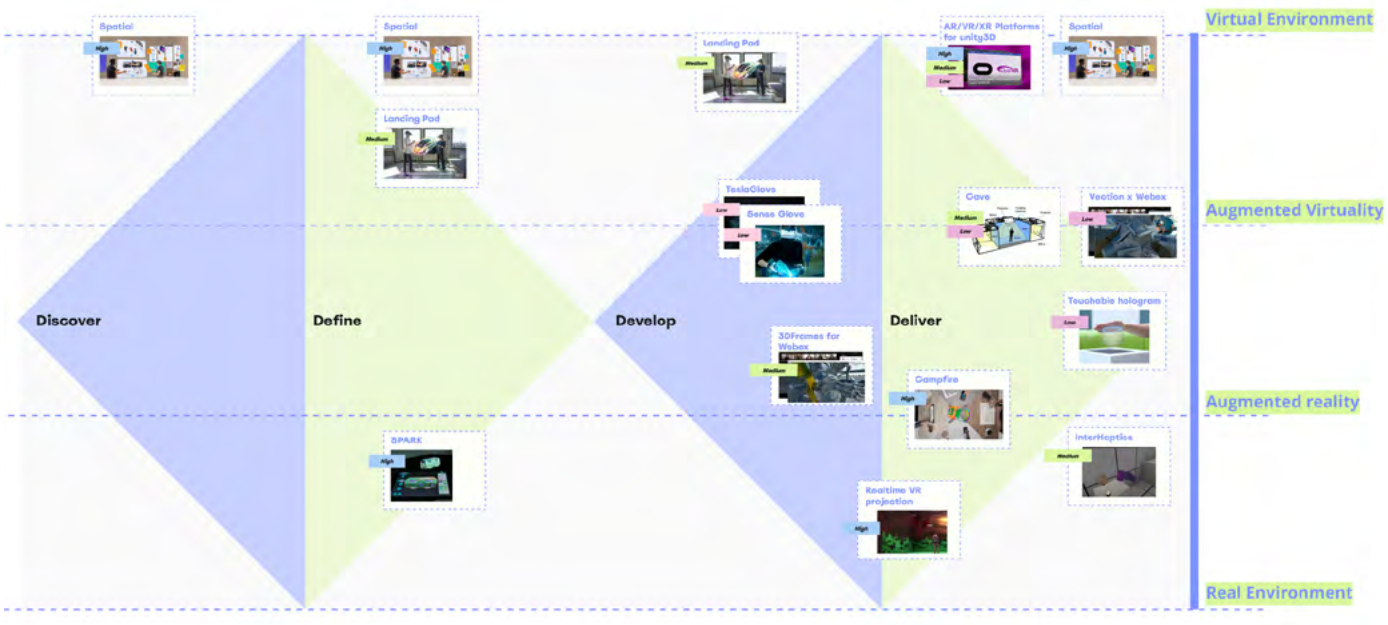

Figure 6. The mapping of the case studies on the double diamond model. The vertical distribution of the case studies is determined by their position within the Milgram continuum (ordered to the right of the diagram). The coloured flag indicates the level of possible collaboration: high blue, medium green, and low pink.

3.4 Implementing XR Tools for Education

Reflecting upon the utility of the most user-centric tools, the research team endeavoured to incorporate specific tools and devices into the academic curriculum, focusing on integrating XR within the educational sphere. This initiative aimed to devise and implement strategic action plans to discern the potential roles of XR in enhancing pedagogical practices. The investigative foray included conducting experiments with a second-year undergraduate cohort from the Product Design programme. AR visualisation software was introduced during the concluding phases of a Digital Representation Studio, categorised within the Showcase cluster. Additionally, students enrolled in the Specializing Master course in Transportation & Automobile Design (Poli.design, n.d.), were engaged in trials involving immersive Virtual Reality VR tools for the evaluative assessment of car interiors, alongside AR tools for the examination of car exteriors, aligning with the Review Together Cluster.

The insights garnered from this project have helped establish an elective course for Master of Science (MSc) degrees in engineering and design. This course is meticulously designed to equip students with an in-depth understanding and practical competencies in XR methodologies and tools. It aims to empower students to create virtual replicas of design solutions for industrial products throughout the various stages of the product development process.

Particular emphasis is placed on XR technologies that are particularly efficacious in representing design solutions during the conceptual and embodiment design phases, thereby fostering the creative process. In mid-2023, the project expanded its horizon by creating a small Virtual Lab. This laboratory is specifically tailored for students pursuing the Industrial Engineering-Design and Architectural Design degree at the XJTU-POLIMI Joint School of Design and Innovation (Polimi, n.d.). This venture represents a significant stride towards embedding XR technologies within the academic framework, facilitating hands-on learning and experimentation.

The forthcoming phase entails the structured evaluation of devices available within collaborative design sessions. Acknowledging the limitations inherent to these devices, conducting tests with designers in an organised setting is anticipated to yield direct feedback from end-users and validate the research findings. Such collaborative testing sessions, conducted within a virtual environment, are poised to delineate the boundaries and unveil XR's opportunities, thereby contributing to refining XR applications in design education and practice.

4. Results

The mapping exercises undertaken within this research have produced insights into the predominant tools that facilitate collaboration across various phases of the design process. An in-depth examination of the interplay between the analysed XR case studies and the principal tools employed during these collaborative stages has led to conclusions concerning the potential for the widespread integration of these tools into collaborative practices.

Recent advances in XR, which encapsulates VR, AR, and MR, have significantly increased the capacity for intuitive multi-user interactions within both co-located and remote settings. This growing technology affords a more enriched social presence through multimodal communication channels, elevating collaborative experiences and augmenting the quality of user experience and task-specific performance.

The analytical synthesis and consequent mapping of the case studies have facilitated their classification into four distinct clusters, each representing an application of XR technologies within collaborative contexts in the product design field:

1. Augmented Meeting. This cluster encapsulates virtual environments designed to enhance the immersive attributes of meetings, wherein participants can be partially or fully immersed. This category underscores the role of XR in transforming traditional meeting spaces into more engaging and interactive spaces. This cluster of XR technologies can be activated during all phases of the design process (Discover, Define, Develop, and Deliver);

2. Design Together. This category is characterised by a shared virtual experience accessible simultaneously to multiple users. It has proven especially effective in the collaborative design and modelling of complex products, demonstrating the profound impact of XR on facilitating collective creativity and problem-solving. This cluster of XR technologies can be activated during the central phases of the design process (Define and Develop), during the concept definition;

3. Review Together. Concentrating on the collaborative presentation of ideas, this cluster facilitates a unified user perspective, enabling the collective review and feedback process. It exemplifies the utility of XR in streamlining communication and enhancing the coherence of collaborative review sessions. Within this cluster, case studies in AR or VR can be found. This cluster of XR technologies can be activated during the final phases of the design process (Develop and Deliver);

4. Showcase. While this dimension may exhibit collaborative elements, it primarily functions as a platform for showcasing outcomes during the delivery phase or displaying products throughout the testing phase. This cluster illustrates the versatility of XR as a tool for demonstrating achievements and facilitating stakeholder engagement. Within this cluster, case studies in AR or VR can be found.

These insights explain the multifaceted applications of XR technologies within collaborative scenarios, highlighting their transformative potential across various dimensions of stakeholder interaction and project evolution. The emergent classification not only offers an understanding of the scope and efficacy of XR in enhancing collaborative activities but also lays the groundwork for future explorations into integrating these technologies within the broader landscape of design and development processes.

5. Discussion

While exploring the XR technologies, it becomes imperative to critically assess the landscape, particularly to demystify the overstatement that often surrounds emerging technologies. A discerning analysis reveals several aspects that deserve consideration (Ashtari et al., 2020).

Firstly, there is a noticeable trend within the domain of XR technology wherein new terminologies are frequently introduced to describe what essentially amounts to the same underlying technology. This proliferation of terminologies and the launch of new devices that exhibit only minor enhancements over their predecessors contribute to a landscape marked by confusion and redundancy. Such a scenario often complicates distinguishing genuine innovation from mere incremental updates (Nebeling, 2020).

Furthermore, promotional materials associated with XR technologies frequently suffer from a tendency towards over-promising. Videos and advertisements showcasing these technologies often portray capabilities and experiences beyond the reach of current implementations. This practice sets unrealistic expectations and obscures these technologies' progress and potential limitations.

Among the critical factors that significantly impact the efficacy and immersion of XR experiences are the display resolution and the field of view. These elements are paramount in defining the quality of the virtual or augmented reality experience, influencing the user's sense of presence and immersion within the digital environment. While many technical aspects of XR technologies are witnessing rapid advancements, these fundamental features continue to serve as benchmarks for assessing the maturity and capability of XR devices (Poulin et al., 2024).

Advancements in user interaction modalities, particularly hand, finger, and eye tracking, have reached a level that is now considered standard and performs quite effectively. These developments have greatly enhanced the intuitiveness and responsiveness of XR systems, allowing for more natural and engaging user experiences.

Despite these advancements, it is crucial to acknowledge that XR technologies are still subject to significant technical and design limitations. These constraints often manifest as less-than-optimal user interfaces, limited content availability, and challenges integrating virtual elements with the physical world (Speicher et al., 2019).

Moreover, the capability for environmental understanding, a critical component for creating convincing and interactive augmented reality experiences, remains relatively rudimentary. Current systems often struggle to interpret and respond to complex physical environments accurately, limiting AR applications' scope and realism.

In conclusion, while XR is expanding with potential, understanding its current state reveals a mix of rapid advancements and persistent challenges. This interplay of progress and limitation defines the current frontier of XR technology, highlighting the importance of tempered expectations and continuous innovation in overcoming the hurdles that lie ahead.

Only in some technologies or devices, which may be the case with the new Apple Visor Pro (Apple, 2023), released in June 2023, does the technology leap forward. In the case of Apple, in addition to improvements on the "visor" system by inserting various features already in use on other devices, the most significant new paradigm is represented by the possibility of gradually varying the immersion of the virtual environment between fully immersive or augmented.

6. Conclusion

This research has provided valuable insights into the potential applications and challenges of integrating such technologies into the design process, demonstrating that XR technologies offer promising solutions for remote collaboration, enhanced communication, and enriched design experiences.

This research has highlighted the transformative potential of XR in redefining collaborative design practices. The classification of XR case studies into distinct clusters, including Augmented Meeting, Design Together, Review Together, and Showcase, underscores the versatility and efficacy of XR tools across various phases of the design process. The findings of this research serve as a foundation for future exploration and innovation in integrating XR technologies within design education and practice. By fostering interdisciplinary collaboration, facilitating hands-on learning experiences, and addressing the evolving needs of design professionals and students, XR technologies promise to revolutionise how designers conceive, create, and collaborate on design projects.

While this research has provided valuable insights into integrating XR technologies in collaborative design sessions, it is essential to acknowledge several limitations. One limitation is the technology evolution: XR technologies are rapidly evolving, with new devices, platforms, and applications continually being developed. This research may become outdated as newer technologies emerge, potentially impacting the relevance and applicability of its findings over time. The findings of this research may be specific to the context in which the study was conducted.

Also, methodological limitations should be considered. The research methods employed, such as case studies, workshops, and literature reviews, may have inherent limitations, such as sampling biases or subjectivity in data interpretation. Future studies may address these limitations by broadening the investigation scope and considering the technology's long-term implications. Thus, the long-term impact of integrating XR technologies into design education and practice remains to be determined and solved by research. It is still being determined how these technologies will evolve, how practitioners and educators

will adopt them, and their lasting effects on design processes and outcomes. Nevertheless, this research provides a valuable starting point for further exploration and advancement in the field of XR technologies in collaborative design sessions by providing points for reflection and analysis that provide insights for future research.

KEYWORDS | CRAFTSMANSHIP, AUGMENTED REALITY, IMMERSIVE LEARNING, ORIGAMI, KNOWLEDGE TRANSFER

ABSTRACT | In the contemporary educational landscape, the integration of mixed reality (MR) marks a significant shift towards more interactive and immersive learning experiences. The benefits include improved spatial awareness, a more context-specific and action-based experience and guidance, isolation, and focus. A current gap exists between manual operation and virtual assistance, where the actions could be supported in their embodied, physical context. Thus, this paper investigates the influence of MR on the learning process, particularly in the acquisition of craftsmanship skills, using origami as a case study. This research focuses on assessing how these technologies enhance understanding, engagement, and skill acquisition in origami, a craft requiring precision, patience, and spatial insight. The study encompasses a controlled experiment with five product development students with varying levels of origami and VR experience, assessed in a pre-test skill-level survey. They use a custom-designed MR application with the Meta (formerly known as Oculus) Quest VR head mounted display (HMD) to learn how to make the "exploded vertex" model, a model representative of David Huffman's curved-crease folding techniques. This headset provides a pass-through option with an improved camera quality. The experiment is structured into six phases, including VR headset adjustment, alignment, drawing, instructional video and 3D model interaction, origami making, and a final satisfaction assessment. These are supported by an AR-assisted visualization presenting step-by-step guidance projected on the physical paper underneath, a prerecorded instructional video, and a 3D model to be grabbed and viewed from all angles. The results indicate that MR significantly enhances the learning experience, offering real-time guidance and a deeper understanding of spatial relationships crucial in origami. Increased engagement and personalized learning adjusted to the individual pace were noted by the participants. However, the impact remained nuanced, where prior origami experience aided in overall performance within the VR environment, it did not translate consistently into higher precision. The leap to MR, despite challenges like visual distortion caused by the quality of the Meta Quest 3, reveals the potential of these technologies in enhancing traditional learning methods. This paper aims to highlight the capabilities and limitations of MR as educational assistive technology. Underscoring the importance of balancing novel technological approaches with traditional methods, areas for future research might include long-term skill retention and optimization for diverse learner demographics.

1. Introduction

Integrating technology into educational and skill development processes has been increasingly prominent in the last few years. One of these emerging technologies that has gained attention in this context is augmented reality (AR). Augmented reality is a technology that blends the real-world environment with digital information, such as a virtually created object, creating an immersive experience for users. The difference with virtual reality (VR) is that the user is then fully enclosed in a virtual environment. Furthermore, it is necessary to acknowledge the difference between AR and mixed reality (MR). While AR provides a view of the real world with an overlay of digital objects, in MR these physical (user or object) and digital elements can interact (Tremosa, 2022). Acquiring new skills and the potential to enhance learning experiences has made this a subject of significant interest, especially in craftsmanship and hands-on skills acquisition. For instance, spatial awareness allows a person to visually discern the spatial relationship between two or more objects, including their connection to themselves. This capability has been confirmed to improve in correlation with the aforementioned technologies (Azarby & Rice, 2022).

Augmented reality learning could enhance students' understanding of concepts and processes compared to the traditional teaching materials. Increasing the participants' interest, focus and motivation in learning new skills are critical factors for effective learning (Hung, Chen & Huang, 2017). The hardware technology applied in this research will be the Meta Quest 3, which is a head mounted display (HMD). An HMD is a screen device that is positioned directly in front of the user's eyes through a head-mounted mechanism. This setup allows digital content to be overlaid onto their field of vision (FOV), offering an immersive user experience that has been useful for skills acquisition such as cognitive skills related to comprehending spatial and visual information and knowledge (Jensen & Konradsen, 2018). The Meta Quest 3 was employed over other available options due to superior pixel quality and full color passthrough.

To research how people, specifically Product Development students, acquire hands-on skills through using MR, the focus is put on the craftmanship of origami specifically. Which entails a high degree of skill, precision and patience. Origami, the East Asian art of paper folding, embodies creativity and expression, allowing artists to experiment with a flat sheet of paper and turn it into three-dimensional models (Chen, 2023). Traditionally, origami has been taught through paper books, diagrams and hands-on demonstrations. However, with the advance of augmented reality technology, there is an opportunity to foster revolution in how individuals learn and engage with this ancient art form. Technology has been used before for 3D origami learning. The use of video recording for instance is significant, in which the folding technique is shown (Kustiawan et al., 2021)

This research paper uses an origami model built by David Huffman; a man known for his curved-crease paper models. The initial documented mention of curved crease folding traces back to a Bauhaus student who participated in a course instructed by Josef Albers during the years 1927 and 1928 (Demaine et al., 2011). Huffman’s work is known for its significant field in origami and mathematical geometry, involving complex curved creases. Origami artists and mathematicians use his work to build upon his knowledge and try to develop a theory for Huffman’s knowledge (Demaine et al., 2011).

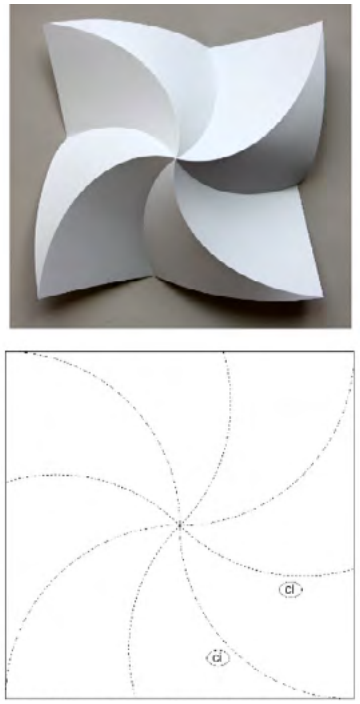

Figure 1. Exploded vertex pattern by Huffman (Demaine et al., 2011).

The specific model chosen for this research is part of a collection of patterns that include an “exploded vertex”, shown in Figure 1 (Demaine et al., 2011). The pattern consists of folding the paper so that all creases (in this exact case: circular arcs which alternate between mountains and valleys) seem to come out of a single point, usually located in the center of the piece of paper. This figure was chosen due to its specific pinching technique that would improve visual significance whether the participants were understanding the process and not just copying folds from instructions as in 2D origami.

The overarching research question in this study revolves around the impact of MR-enhanced learning experiences on the acquisition of craftsmanship skills, with origami as specific focus. Understanding the influence of MR on the overall learning process and engagement of individuals in acquiring such skills can have far-reaching implications in education. Not only in Product Development, including related in-print paper by Garcia (2024). But in numerous fields such as aerospace, mechanical engineering, skills development and even recreational pursuits (Yue, 2023; Turner et al., 2016). Prior research mentions the possibility that immersive technological experiences lead to higher levels of engagement and understanding of complex concepts and spatial relationships (Dede, 2009; Bodzin et al., 2020).

2. Method

The experiment explores the integration of origami and augmented reality in a six-phase process. Each participant first adjusts the headset and gets their first experience with an MR environment. The next phases include the making of David Huffman’s origami shape, with the exploded vertex. The final phase evaluates their satisfaction and completion of the task in comparison with the result of the expected outcome.

The think-aloud method for receiving feedback from the participants was utilized to acquire user insight and action reasoning. The think-aloud method is implemented in research when insights into participants cognitive processes during specific tasks are of importance. By having participants verbalize their thoughts, researchers get to understand the thought processes and decision-making strategies participants go through during their performance (Eccles & Arsal, 2017).

2.1 Participants

The study includes five participants, two males and three females, aged between 19 and 21 years. A set of pre-test questions reveals the following. All are Product Development students with up to three years of CAD experience in classes using SolidWorks, particularly in surface modelling. Their backgrounds in origami and VR experience vary, providing a diverse sample for the experiment. The participants' levels of origami experience ranges from very little or no experience during childhood and a general disinterest to a significant amount of personal engagement, folding during their free time as a hobby. Similarly, their mixed reality experience varies from no prior exposure to quickly using virtual reality to test a few functions and watch a video. More specifically, Participant 1 demonstrates solid origami skills but had limited VR exposure. Participant 2 has moderate origami familiarity and minimal VR experience. Participant 3 possesses basic origami knowledge and engaged in some VR activities. Participant 4 exhibits minimal interest in both origami and VR. Participant 5 has a higher origami skill level but was not actively practising and had no VR experience.

2.2 Apparatus and Materials

Apart from a table and a chair for the participant:

- VR Headset: Meta (formerly known as Oculus) Quest 3;
- MR Application: Specifically designed for the experiment within the game engine Unity and not based on existing layouts. It features functionalities for aligning paper with a virtual template, drawing over lines on paper, viewing instructional videos, and interacting with 3D origami models;
- Origami Paper: A4-sized paper cut in 21cmx21cm for origami crafting;
- A pen and standard stationery for the drawing phase.

2.3 Think-Aloud Method

During the experiment, participants are instructed to verbalize their thoughts, actions and feelings in real-time using the think-aloud protocol. This technique aims to capture their cognitive processes, problem-solving strategies and immediate reactions to the MR environment.

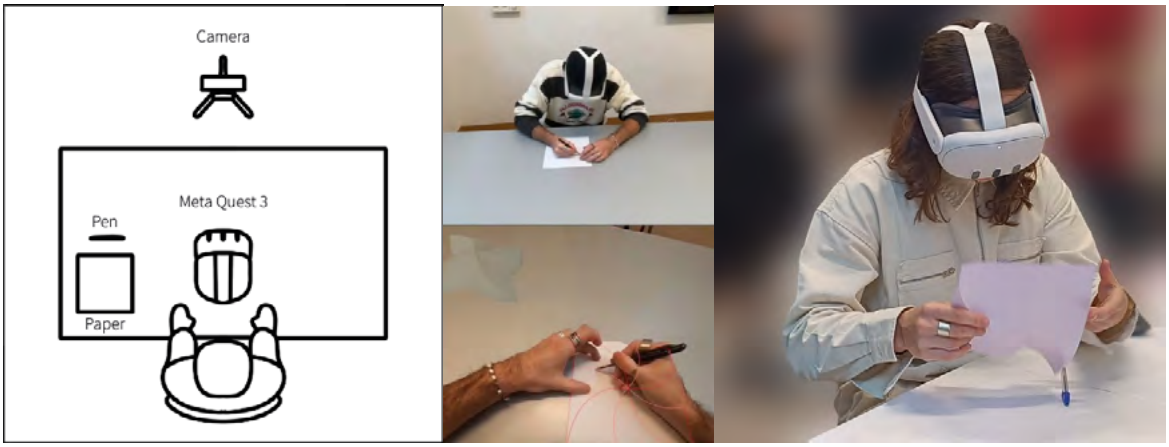

Figure 2. The test setup (left to right: illustrated top view; synchronized camera viewpoint (top), headset viewpoint inside headset (bottom); folding in action).

2.4 Procedure

The experiment is structured into six phases and pre-formed in an aforementioned setup, Figure 3 highlights the distinction between virtual and physical elements:

Phase 1: VR Headset Adjustment and Initial Task: Participants are asked to put on the headset. This phase assesses how participants adjust to the VR headset and their initial reactions, focusing on ease of use and interaction with the AR environment.

Phase 2: Alignment Task: Participants are instructed to take a piece of paper and align it with the template, visible in augmented reality. This phase involves observing precision, strategy and any adjustments made.

Phase 3: Drawing Task: Participants are asked to take a pen that is on the table and draw over the lines, visible in augmented reality. By doing so, the participants pre-crease the paper, effectively creating a guide for the folds in the next step. This phase focuses on their accuracy, method of tracing, and level of concentration. Time taken and normalized accuracy are documented.

Phase 4: Instructional Video and 3D Model Interaction: Participants are instructed to watch a small repeating video clip, showing the correct folding technique for the origami model. After which they are told to look at and grab a virtual 3D model of the final origami model. This phase focuses on observing engagement level with both the video and the 3D model, interaction style and comprehension of instructions.

Phase 5: Origami Making: Participants are asked to start making the origami model with no further instructions. This phase focuses on skill, technique, reference to instructions (technique video and the 3D model) and problem-solving strategies.

Phase 6: Completion and Satisfaction Assessment: Participants are instructed to end the test once they feel satisfied with their result or approve of a stalemate in their progress. This phase assesses when participants decide they completed the task and their satisfaction with the result, comparing the result with the expected outcome and noting the duration of completion.

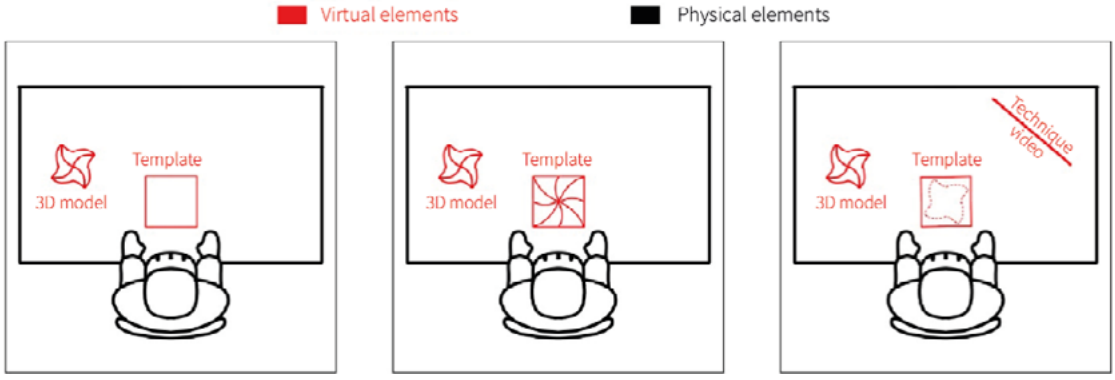

Figure 3. Visuals visible for the user in phases from left to right: phase 1, 2; phase 3; phase 4, 5, 6.

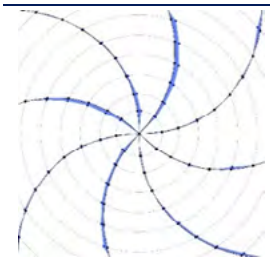
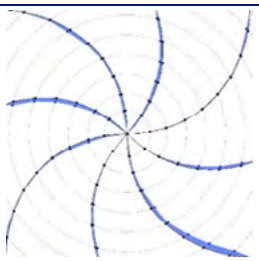
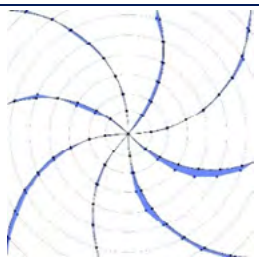
2.5 Post-Experiment Interview

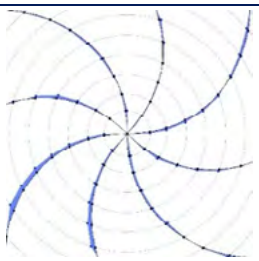
A post-experiment interview is conducted to gather feedback on the overall experience, challenges faced, perceived usefulness of the MR technology in learning origami and any suggestions for improvement of the overall experience and the MR and real-life setup. The questions are inspired by the NASA Task Load Index (NASA-TLX) (Galy et al., 2018).

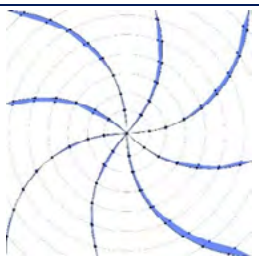
2.6 Data Collection and Analysis











Quantitative data includes specific task times, normalized accuracy for the drawing task, and final scores of the origami models. Qualitative data encompasses observational notes from each experiment phase, think-aloud narrations and insights from pre- and post-experiment interviews. This comprehensive data collection aims to correlate participant backgrounds, in-task verbalizations and post-experiment reflections with their performance and overall experience. The final model score is decided by comparing the participant's result with the example model and placing them on a scale from zero to ten, defining 0 as a flat sheet of paper, and 10 as a perfectly folded model.

To assess the accuracy of each participant's drawings, we employ a method that quantifies the area between the participant's drawn lines and the template lines (Figure 3) shown in the overlay. This area represents the deviation from the desired line and serves as a measure of drawing accuracy.
We defined 100% accuracy, as a scenario where the participant's line perfectly overlays the mixed reality template, resulting in an area of zero deviation. Conversely, the worst-case scenario, representing 0% accuracy, was defined by the maximal possible area of deviation that could occur within the confines of the experiment's setup. To calculate the area of deviation, we digitize each drawing and apply image analysis software to measure the area between the drawn and template lines. The resulting area measurements are used to calculate the accuracy percentage by inversely scaling the measured area between the predefined maximum (0% accuracy) and zero (100% accuracy).

3. Results

Participants engaging with 3D models in MR report a more engaging learning experience and better understanding of spatial relationships. The immersive quality influences the participants' comprehension of complex shapes through the grabbable 3D model. The overlay for the drawing tasks received multiple enthusiastic responses from participants one, three, four and five. Stating that without the overlay they would have encountered more issues. Regarding origami skill acquisition, participants with prior experience demonstrated greater confidence in the virtual environment, though it did not necessarily improve drawing accuracy. Limited MR experience did not hinder performance significantly, but familiarity influenced task approaches. Participants displayed varying degrees of adaptation to the MR environment. In perceptions and interactions with VR features, participants recognized the utility of VR in enhancing learning, despite facing challenges like visual distortion. Quantitative results showed variability in drawing accuracy, differing approaches in task times, and variations in final model scores, reflecting differences in task execution and product quality. These can be found in Table 1.

Table 1. Point-to-point analysis, Think Aloud Method and Video analysis.

Participant 1	Participant 2	Participant 3	Participant 4	Participant 5
				
Self-rated origami experience 7/10, limited VR experience	Self-rated origami experience 3.5/10, minimal VR experience	Self-rated origami experience 4.5/10, some VR experience	Self-rated origami experience 2/10, no VR experience	Self-rated origami experience 5.5/10, no VR experience
Phase 1: Adjusted well to VR headset, impressed by the virtual 3D model.	Phase 1: Adjusted well to VR headset with minor distortion noted.	Phase 1: Adjusted well to VR headset with no confusion.	Phase 1: Adjusted well to VR headset with no confusion.	Phase 1: Adjusted well to VR headset, impressed by the virtual 3D model.
Phase 2: Successfully aligned paper with AR template on first try.	Phase 2: Successfully aligned paper with AR template on first try.	Phase 2: Successfully aligned paper with AR template on first try.	Phase 2: Successfully aligned paper with AR template on first try.	Phase 2: Successfully aligned paper with AR template on first try.
Phase 3: Drawing Task - Time taken: 1min 5sec, Normalized Accuracy: 59.18%.	Phase 3: Drawing Task - Time taken: 48sec, Normalized Accuracy: 55.10%.	Phase 3: Drawing Task - Time taken: 20sec, Normalized Accuracy: 53.08%.	Phase 3: Drawing Task - Time taken: 20sec, Normalized Accuracy: 53.08%.	Phase 3: Drawing Task - Time taken: 1min 5sec, Normalized Accuracy: 59.18%.
Phase 4: Watched instructional video, did not pick up 3D model again after initial interaction.	Phase 4: Focused on instructional video, analyzed 3D model thoroughly.	Phase 4: Focused on instructional video, interacted with 3D model.	Phase 4: Focused on instructional video, interacted with 3D model.	Phase 4: Watched instructional video, did not pick up 3D model again after initial interaction.
Phase 5: Successfully picked up folding technique but caused unintentional wrinkles.	Phase 5: Quickly picked up folding technique, noted difficulty in visual focus.	Phase 5: Understood technique but applied it slightly wrong, made adjustments.	Phase 5: Understood technique but applied it slightly wrong, made adjustments.	Phase 5: Successfully picked up folding technique but caused unintentional wrinkles.
Phase 6: Final folding time: 7min 20sec, Final model score: 7/10	Phase 6: Final folding time: 4min 14sec, Final model score: 9/10.	Phase 6: Final folding time: 3min 37sec, Final model score: 5/10.	Phase 6: Final folding time: 3min 37sec, Final model score: 5/10.	Phase 6: Final folding time: 7min 20sec, Final model score: 7/10.

The Normalized accuracy ranges from 40.74% to 59.18%, indicating variability in precision during the drawing task (Figure 4).

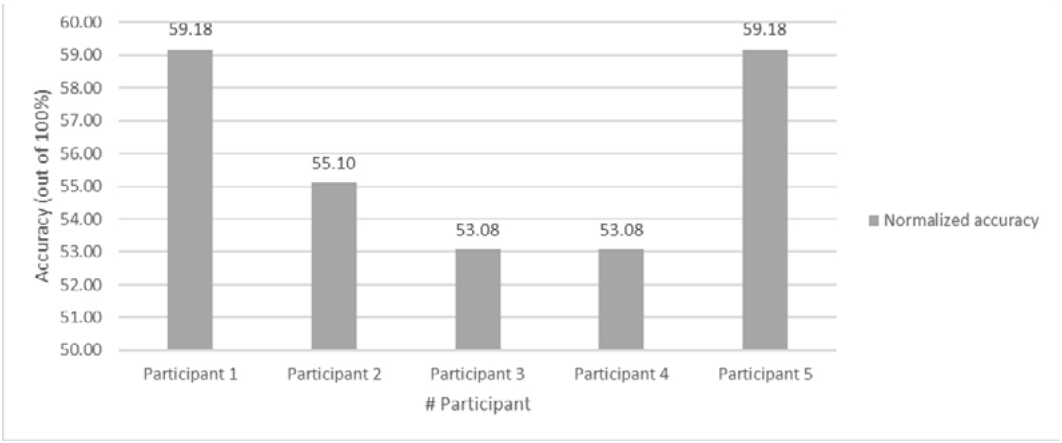


Figure 4. Normalized accuracy results.

Figure 5 shows the average time for Drawing Task, which ranged from 20sec to 1min 05sec, showing differences in pace and approach. However, the average time for Origami Making ranges from 3min 37sec to 7min 20sec, suggesting a generally consistent engagement with the task.

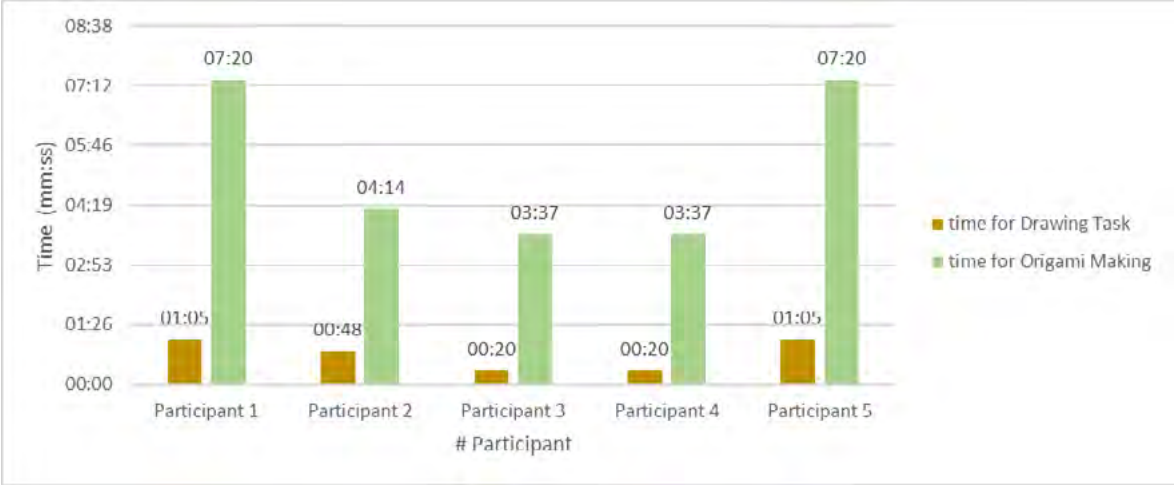

Figure 5. Time-based performance.

The final model scores, depicted in Figure 6, vary from 5/10 to 9/10, reflecting the differences in overall task execution and final product quality.

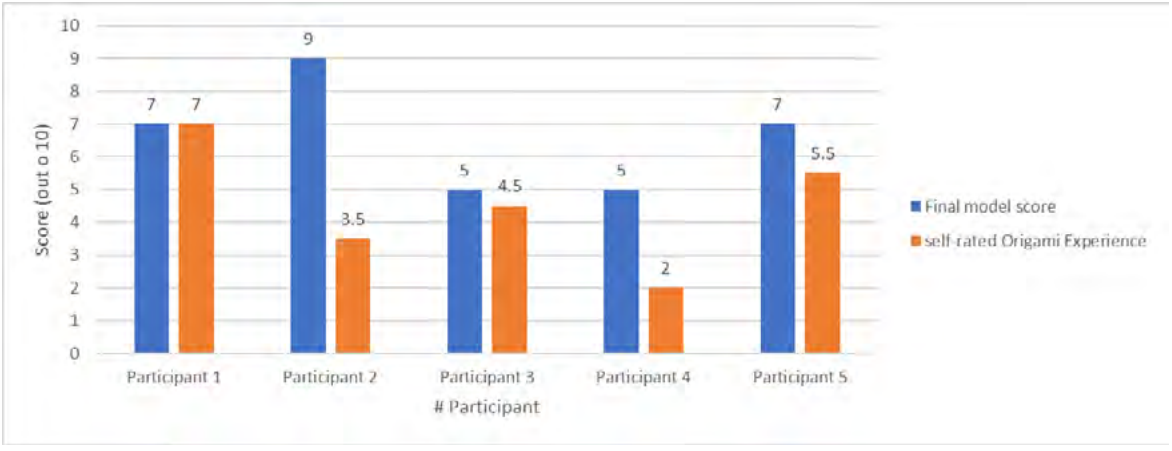

Figure 6. Quality-based results.

The post-experiment interview results indicate participants with higher self-rated origami experience, like Participant 1, showed more confidence and adaptability in handling tasks, despite initial VR adjustments. The participants additionally perceived the experiment to be mentally challenging. Only slight complaints purely about hardware-related issues were made such as warping of the view and dimness. The satisfaction of the origami creation result was mixed, some participants were not happy with their origami since their envisioned result was of higher quality. However, most considered their result fair enough and found the visual guidance helpful. The majority of the participants also found detail work tougher to perform than the general actions. Based on the instruction given through the MR setup, most participants were confident that they could recreate a similar origami design. Both with and without a headset, based on the gained knowledge. The repetition to perform the same sort of craft process with the use of the technology was however divided. Half of the participants saw this more as a one-time experience in its current state. In the end also half of the participants stated that they would use the virtual reference more. They focused most attention on the tutorial video, keeping the virtual reference more in mind would result in an improved execution and visually appealing origami product.

Across all participants the mixed reality setup was found to be a useful tool for certain aspects of the task, such as line drawing, but also introduced challenges like visual distortion and difficulty in detailed work.

4. Discussion

This study's findings contribute to the growing body of research on mixed reality (MR) as an educational tool, particularly in the realm of craftsmanship and skill acquisition. The immersive and interactive experiences provided by MR have demonstrated significant potential in enhancing the learning process for complex skills such as origami. However, this exploration extends beyond the mere affirmation of these technologies' effectiveness; it delves into the nuances of their impact on diverse learners.

The study underscores the benefits of immersive learning environments. MR's ability to overlay instructional content onto the physical world creates a more engaging and intuitive learning experience. This finding aligns with prior research indicating that immersive technologies can lead to higher levels of engagement and a deeper understanding of complex concepts. The interactive nature of these technologies, as evidenced by the learners' ability to manipulate 3D models, plays a crucial role in understanding spatial relationships – a key component in origami.

The findings suggest that learners benefit from progressing at their own pace, echoing the conclusions drawn in similar studies (Srithar & Selvaraj, 2015). This aspect of technology-enhanced learning is especially crucial in educational settings where learners' abilities and learning styles vary widely. The influence of prior origami experience and familiarity with VR on task execution was a critical aspect of this study. Interestingly, while prior experience in origami seemed to boost confidence in VR environments, it did not invariably lead to higher precision in skills requiring fine motor control. This observation raises questions about the transferability of traditional skills to technologically mediated environments, suggesting an area ripe for further investigation.

This study has its limitations. First, the sample size and demographic diversity of participants may limit the generalizability of the findings. Second, the study's duration did not allow for an assessment of long-term skill retention or the effectiveness of these technologies over extended periods.

Furthermore, the visual quality of the pass-through video was limited: participants frequently mentioned issues like pixelation and distortion, which occasionally broke the immersion and made tasks like line drawing more challenging. This underscores the current technological limitations of MR in delivering a consistently seamless and realistic experience.

5. Conclusion

Our study provides an examination of how mixed reality technologies impact the acquisition of craftsmanship skills. Focusing on origami as a test case, the study demonstrates the dynamic and engaging learning environment immersive technologies can create, offering significant advantages over traditional instructional methods. The use of MR allows for the overlay of instructional guides in the physical world and the manipulation of 3D models in real-time, enhancing the learner's grasp of complex shapes and spatial relationships critical in origami.

The effectiveness of MR in skill acquisition is influenced by factors such as the learner's prior experience with origami and their familiarity with immersive technology. While previous experience may increase confidence and adaptability, it does not necessarily correlate with higher precision or more effective performance. This underscores the importance of well-designed MR orientation programs to maximize the benefits of these technologies in learning contexts. Despite initial challenges like visual distortion or focusing difficulty, learners generally maintained their performance levels, suggesting that the potential benefits of MR in education outweigh the initial hurdles. The quantitative analysis shows variability in task outcomes, possibly implying the need for personalized learning approaches to accommodate diverse learning styles and paces. The post-experiment interview reveals that the line template was perceived exceptionally well, having a positive impression on all the participants and them stating its significant added value over the traditional video instruction. Most of the participants were not directly satisfied with the result of their origami creation, however found the MR experience pleasant and could see the implementation in the future with optimized visual capability and more support around the entire process in a step-by-step fashion of the craft.

By integrating MR with traditional learning methods, educators and learners can benefit from a more inclusive, adaptable, and engaging educational experience. Future research could explore longitudinal impacts of MR on skill acquisition and retention. Studies could also investigate how these technologies can be optimized for different learner demographics, including age groups and varying levels of technological proficiency. Furthermore, comparative studies between immersive learning and traditional approaches could yield deeper insights into the efficacy and adaptability of educational tools.

KEYWORDS | USER EXPERIENCE, INTERFACE DESIGN, DIGITAL INTERACTIONS, MUSIC PLAYING, RUNNING

ABSTRACT | User interfaces for music devices and streaming platforms often neglect the needs of physically active users, who require interfaces optimized for dynamic activities like running. To address this, interfaces must offer intuitive controls, non-intrusive feedback mechanisms, and compatibility with runners' movements. Running, a popular activity for physical and mental well-being, combined with music listening, poses unique challenges and advantages. This study investigates runners' behaviors and interactions with various interfaces, using eye-tracking technology and interviews with 10 participants. The findings highlight the challenges runners face in managing multiple devices while running and emphasize the need for intuitive design.
The research explores the tension between expressive and utilitarian design in user interfaces, especially concerning digital music platforms for runners. It offers insights to enhance user experiences and bridge the gap between technological systems and user needs. By addressing these challenges, the study contributes to a deeper understanding of the intersection between running, music devices, and interface design, guiding future design developments for a more seamless and user-friendly experience.

1. Introduction

Music listening and running are two widely embraced activities that offer distinctive experiences for enthusiasts of both pursuits. Casual running is often pursued for reasons such as weight management, fitness, and meditative purposes (Bood et al., 2013) typically requires no specialized equipment. On the contrary, running with music can disrupt the overall running experience by requiring runners to carry supplementary devices, such as a mobile phone or music player, and a channel like a headphone or earphone, along with an accompanying audio output channel like headphones or earphones. The music control features can pose challenges due to physical movement, external factors, and the extra weight and bulk of the devices (Terry et al., 2012). Despite these challenges, many runners opt to integrate music into their routines to make the experience more seamless and enjoyable (Jebabli et al., 2020).

User interfaces for music devices and streaming platforms often overlook the needs of runners, focusing on static use rather than the demands of dynamic activities like running. Prioritizing usability for runners is crucial, necessitating interfaces that seamlessly integrate with their activity without interruption. This requires intuitive controls, non-intrusive feedback mechanisms (including e.g., auditory tones or vibrations) that confirm user actions without interrupting concentration, and compatibility with runners' movements. Although current mobile music streaming platforms and headphones offer diverse features to enhance the running experience with music, the overall experience can be ambiguous from the runner's perspective. This study focuses on the overall experience and specialized interactions between users and tangible as well as digital interfaces facilitating music for runners.

The researchers claim that by adapting music control interfaces for running activities, it is possible to optimize the user experience and create a safer and more enjoyable environment for runners. Through this study, the researchers aim to bridge the gap between technology and recreational activities, aligning them in a way that enhances rather than hinders the runner's experience. The motivation to explore and innovate in the field of music control interfaces for runners is driven by the belief that advancements in interface design can significantly contribute to optimizing performance, safety, and overall satisfaction during running sessions.

2. Running with Music

Running and music share a unique relationship, as running serves as a physical activity engaging individuals across various age groups and fitness levels. The running experience is multifaceted, encompassing physical sensations, bodily responses, psychological effects, emotional benefits, social aspects, and challenges. Crucial physical changes, such as alterations in heart rate, breathing patterns, and energy expenditure, are essential for meeting the heightened demands placed on the cardiovascular and respiratory systems (Foster et al., 2019). From a psychological perspective, running stands out for its positive effects on mental well-being, with research showing that running can induce a "runner's high" and reduce symptoms of depression and anxiety (Boecker et al., 2008; Dietrich and McDaniel, 2004). Regular running has been associated with enhanced self-esteem, improved cognitive functioning, and reduced symptoms of depression and anxiety (Hassmen et al., 2000; Stults-Kolehmainen and Bartholomew, 2012). Running can also evoke a wide range of emotions, such as joy, accomplishment, and empowerment (Lane and Wilson, 2011). These emotional benefits extend beyond immediate experience, contributing to overall emotional well-being, self-esteem, and body image (Sabiston and McDonough, 2009; Tiggemann and Zaccardo, 2018). Socially, running fosters a sense of belonging and camaraderie among runners, while challenges include the inherent risk of injuries and fatigue (Krabak et al., 2011; Niven et al., 2020).

Despite these challenges, the rewards of running are significant and often outweigh the challenges. Running provides a sense of accomplishment and achievement, contributing to improved fitness, maintenance of a healthy weight, and the overall promotion of physical well-being. Additionally, engaging in running can foster personal growth, heightened self-confidence, and a sense of empowerment (Moore et

al., 2020). The running experience encompasses physical, psychological, emotional, and social dimensions, offering a holistic perspective on its impact on individuals. By considering these dimensions, individuals can gain a deeper understanding of the holistic impact running can have on their physical health, mental well-being, and social connections.

Music proves to be a powerful motivational tool, especially in the context of exercise and physical activities. Studies have shown that music has the capacity to elevate affect, reduce perceived exertion, improve energy efficiency, and amplify work output and when chosen for its motivational qualities, music can exert a magnified positive impact on both psychological state and performance (Karageorghis and Priest, 2012). Motivational music is characterized by a fast tempo and strong rhythm, boosting energy levels, and prompting physical activity. It can synchronize with the body's movements, leading to improved performance and endurance (Bood et al., 2013). Listening to motivational music not only stimulates physical activity, but also enhances mood, reduces perceptions of exertion, and brings about changes in arousal. It can also serve as a valuable distraction from pain and fatigue, allowing individuals to overcome challenging moments during exercise (Bood et al., 2013). Music's emotive quality can create a positive affective state even in negative psychological circumstances (Van den Tol and Edwards, 2011). By understanding the motivational qualities of music and selecting appropriate tracks, individuals can harness the power of music to enhance their motivation, performance, and overall exercise experience.

The combination of the two activities 'running-with-music' generates a distinctive synergy that enriches the overall running experience. The rhythmic nature of running aligns well with the rhythmic qualities of music, creating a harmonious and immersive experience. Music, serving as a powerful motivator, provides a steady beat that helps runners to maintain their cadence and pace. It can also uplift spirits, and serve as a distraction from physical discomfort, enabling runners to push through challenging moments with greater resilience.

The incorporation of music into running routines has become increasingly popular, as runners recognize the positive impact it can have on their performance, enjoyment, and overall well-being. The impact of music on running performance has been explored in different contexts. For example, one study found no significant differences in heart rate and perceived exertion with and without music (Cabral et al., 2022). Nevertheless, distinct levels of music information were found to affect running performance, with participants covering a greater distance when there was more music information, particularly in synchronous conditions (Ramji et al., 2016). Auditory-motor synchronization represents a crucial dimension of the intersection between running and music. The beat and tempo of music can synchronize with the body's movements, leading to improved performance and endurance (Bood et al., 2013). Research indicates that synchronizing movement tempo to acoustic stimuli, such as music or metronomes, can positively impact running performance. Music's influence on psychological state during running is profound, shaping mood, arousal levels, and attentional focus. Karageorghis and Priest (2012) emphasize the positive effects of music on psychological state and performance, highlighting its capacity to elevate affect, reduce perceived exertion, and improve energy efficiency. Running with music offers a dynamic and engaging experience that combines the physical benefits of running with the emotional and motivational power of music. Although, some studies present contradictory findings, suggesting that the effects of music on running may vary depending on factors such as exercise intensity and individual preferences, additional research is needed to explore the specific mechanisms underpinning the effects of music on running and understand individual differences in response to music.

3. Research Methodology

The research outlined in this paper seeks to explore ways in which music platforms and their communication/interaction between headphones/earphones can be better designed to enhance the music listening experience of amateur runners while running outdoors. The study explores the user experience with the interfaces that runners use. To closely observe and inquire into runners' experiences, it was deemed essential to conduct in-context fieldwork where participants are observed while running with music devices. Therefore, a fieldwork setup was established, providing a setting where runners actively

engage in running with their devices. In addition, the participants wore an eye-tracking device to gather supplementary information on their interactions with the interfaces of music listening devices or app screens. Accordingly, a three staged fieldwork was set up consisting of the following three parts: i) Pre-Running-Interviews; ii) Running Activity on a Track, and iii) Post-Running Interviews. In total, ten participants were secured. Each part of the fieldwork was carried out with each participant individually.

Pre-Running-Interviews, was planned as an interview section in which participants were asked about their running habits, specifically their routines for running with music, the devices they utilize, and platforms they interact with. Additionally, the participants were briefed with more detailed information about the implementation of the study before the commencement of the fieldwork.

Running Activity on a Track, constituted a fieldwork procedure involving 10-15 minutes of running activity around Middle East Technical University's outdoor running track, incorporating the use of a wearable eye tracker. The participants carried their headphones/earphones and technological devices to enable music listening while running. The participants were given commands regarding music control during the running activity, and the sequences of performing commands were recorded through an eye-tracking device. The primary objective of this activity was to gain insights into participants' experiences with physical and digital interface components, aiming to uncover any challenges that participants encountered in relation to these interface elements.

Participants were given a period to wear eye-tracking glasses, wear their own headphones that they brought, and keep their smartphones connected to digital music listening platforms. When the participants were ready, the running activity commenced. Participants began running around the track, with each round covering approximately 410 meters. Throughout their run, eight banners, each featuring a distinct music playback commands (i.e., start the playlist; turn the volume down; turn the volume up; change the song; pause the song; resume the song; change the playlist; and finish the playlist) were strategically lifted up by the researcher in varied orders and at different locations on the running track to prevent participants from forming expectations based on a regular order. The commands were reinforced with both corresponding icons and written text. The eight commands were chosen by estimating the music playback controls that are likely to be interacted with the most during a run. Since more complex music playback controls, such as liking/disliking a song, preparing a playlist, following lyrics, are less likely to be used while running, the study only focused on the eight commands.

Figure 1 provides a diagrammatic representation of how the commands were displayed on the track, with each participant receiving a different command combination. Upon the completion of all eight commands (approx. four rounds around the running track), the running activity concluded. Participants were given a short break to rest and remove the equipment they used. Subsequently, they were escorted to the post-running-interviews, marking the final part of the fieldwork.

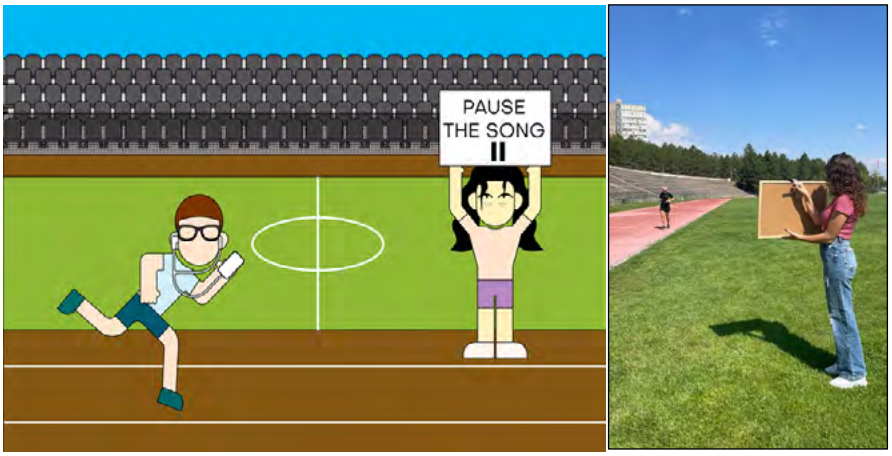

Figure 1. A representation of how the researcher instructed the participants on music playback commands was through a banner displayed on the track.

Post-Running Interviews, were conducted immediately after the running activity with the aim of gathering feedback on both the activity itself and the commands provided to participants. Participants were specifically inquired about the advantages and challenges that they experienced with the devices and interfaces to carry out the commands while running. Their recommendations for the design of product and digital interfaces were also sought. Additionally, participants shared their thoughts on the experience with the wearable eye tracker.

4. Results

The semi-structured interviews conducted before and after the running activity provided insights into the runners' experiences and expectations regarding their music listening routines and the interfaces they interacted with while running. Additionally, the running activity provided a measurable means of capturing the steps in the runners' experience of performing music playback commands and their corresponding execution times with the help of eye-tracking technology.

During the pre-running Interviews, participants disclosed details about their music listening routines and habits while running, highlighting the characteristics of the devices and interfaces they used. In the post-running Interviews, they evaluated the challenges encountered in performing the music playback commands during the field activity and elaborated on the underlying reasons.

The difficulty ratings of the music playback commands conveyed in the post-running Interviews were arranged in tabular format, and their respective percentage analyses were indicated. The fieldwork results and analysis are presented together with the design insights about the current digital and tangible interface interactions in the context of running and the discussion of the role of eye-tracking technology in capturing runners' experiences.

4.1 Difficulty Ratings of the Music Playback Commands

As mentioned before, during the running activity, participants were asked to perform the music control commands as soon as they encountered them. After they completed the running activity participants asked to rate how easy or difficult it was for them to execute the music playback commands given to them on a 5-point Likert scale [Very easy (1), Easy (2), Moderate (3), Difficult (4), Very difficult (5)] (see Figure 2). In addition, the participants were given multiple-choice questions to find out which commands were challenging and simple to follow.

In the Post-running Interviews, it became clear that the participants had trouble separating related commands into individual evaluations. Therefore, in this section, commands requiring opposite actions were decided to be paired (e.g., 'Volume Up/Volume Down') for easier analyses in contrast to the analysis in the earlier sections where the commands and reaction times to them were analyzed separately (e.g., 'Volume Up' and 'Volume Down').

	Participant no.	P_01	P_02	P_03	P_04	P_05	P_06	P_07	P_08	P_09	P_10	Aver.
Music Playback Commands	Change the Playlist	4	3	4	3	3	5	4	3	3	4	**3.6**
	Change the Song	3	2	4	3	2	2	3	2	1	1	**2.3**
	Pause / Resume the Song	1	1	3	3	1	3	3	1	1	1	**1.8**
	Start / Finish the Playlist	1	3	1	1	3	2	3	1	1	1	**1.7**
	Volume Up / Down	1	5	1	1	1	1	1	1	1	2	**1.5**

Figure 2. Rank order averages of Likert scale scores for music playback commands based on evaluations from 10 participants.

The distribution of responses for music playback commands is as follows (unmentioned scales indicate that none of the participants responded accordingly).

- *Change the Playlist*. 'Moderate' (5/10), 'Difficult' (4/10), 'Very difficult (1/10)'.
- *Change the Song*. Very easy' (2/10), 'Easy' (4/10), 'Moderate' (3/10), 'Difficult' (1/10).
- *Pause/Resume the Song*. 'Very easy' (6/10), 'Moderate' (4/10).
- *Start/Finish the Playlist.* 'Very easy' (6/10), 'Easy' (1/10), 'Moderate' (3/10).
- *Volume Up/Down*. 'Very easy' (8/10), 'Easy' (1/10), 'Very difficult' (1/10).

Participants were asked to identify the easiest and most challenging and commands. The majority of the participants (8/10) found 'Volume Up / Volume Down' the easiest, likely because of the convenience of tangible volume control buttons. They preferred using these physical buttons over navigating digital music platforms on screens, finding them more user-friendly.

In contrast, most participants (9/10) described the command 'Change the Playlist' as the most difficult due to the need for multiple interactions across screens. They mentioned that they could manage commands through their headphones except for 'Change the Playlist'. The participants' statements regarding the easiest and most difficult commands align with the results of the ANOVA analysis of execution times.

4.2 Analysis of the Command Execution Times based on Eye Tracking Data

This section concentrates on the analysis of the execution times of music playback commands, with a specific emphasis on data obtained from eye-tracking. The collected eye-tracking data involved measuring and ranking the time participants took to perform the commands. This ranking aimed to assess the perceived difficulty of the commands obtained from the interviews. At the same time, various screenshots were captured from the eye-tracking recordings. These screenshots facilitated a visual analysis of the participants' commands execution and the duration taken to perform them.

A one-way ANOVA (Analysis of Variance) test was used to determine whether there was a statistically significant difference between the execution times for the commands (discrete groups of data) and, if so, between which pairs of commands. In the test, 'p-value' is commonly defined as '0.05', such that < 0.05 corresponds to the presence of a statistically significant difference between at least one of the test pairs. The ANOVA was run with eight groups, corresponding to the eight music-playing commands, with data from the ten participants in each group (Figure 3). A Tukey's HSD post hoc test was used to identify which (if any) of the pairs from the ANOVA contained significant differences. An online statistics page (Statistics Kingdom, 2023) was used to calculate ANOVA and Tukey's HSD Test.

One Way ANOVA test, using F distribution df (7,72) (right-tailed) detected significant differences between some groups. The post hoc Tukey HSD test revealed the pairs of groups had significant differences. The results of the Tukey HSD test are shown in Figure 4, revealing (in bold text) the following pairs to have statistically significant differences: x1-x2, x1-x3, x1-x4, x1-x5, x1-x7, x1-x8, x2-x6, x3-x6, x4-x6, x5-x6, x6-x7, x6-x8.

Sample Size	Time Interval to Execute the Command (in seconds)							
	x6	x1	x5	x7	x8	x2	x3	x4
Participant no.	Change the Playlist	Start the Playlist	Change the Song	Pause the Song	Resume the Song	End the Playlist	Volume Up	Volume Down
P_01	10.2	18.1	5.8	6.5	2.1	3.7	2.2	2

x7	0.87	1.27	1.45	0.75	**9.51**	0	0.69

Figure 4. Summary of Tukey's HSD Test / Tukey-Kramer Test Results.

Both commands "Start the Playlist" (x1) and "Change the Playlist" (x6) took a significantly slower time to execute then all the other commands, except that no significant difference was found between "Start the Playlist" (x1) and "Change the Playlist" (x6). Apart from these results, none of the other commands had execution times that were significantly slower or faster. For example, the two commands with the shortest execution interval – "Volume Down" (x4) and "Volume Up" (x3)– were not significantly shorter than the other commands. With the help of the fieldwork, both the actions and the statements of the participants showed that the difficult levels of the music controls can be ranked and compared. In the running activity, thanks to the eye-tracking technology, participants' actions were recorded and the time intervals to manage music controls were detected. Also, the post-running-interviews obtained the statements of the participants about the music controls that they executed. For runners who prefer to listen to music while running, the difficulty or ease of music controls can vary depending on their preferences and the interfaces provided by their chosen devices and platforms. However, some general observations were made.

The play/pause button is typically the simplest and most intuitive control for runners. A large, easy-to-press button allows for quick management of music playback without much thought or effort.

Selecting a song and controlling the music can be challenging. Runners find it difficult if the interface is complex or if they have to navigate through multiple screens or menus to find and play their desired music. If a runner wants to search for a specific song, artist, or album while on the move, this can be quite challenging. Typing or voice recognition for searching might not be as accurate or quick as desired. On the other hand, an interface that allows for quick and intuitive music selection and control, such as a simple swipe or tap gesture, can make it easier for runners to manage their music while on the move. Interfaces that offer fine-tuned navigation, such as rewinding or fast-forwarding within a song, can be challenging to use while running. These controls often demand precise touch gestures or screen interactions that are not conducive to a smooth run.

Volume controls are often straightforward, especially when physical buttons or touch-sensitive surfaces are well-designed. Runners can easily adjust the volume to suit their preferences or situational needs. However, there were different scenarios when analyzing the volume control commands. As Figure 5a illustrates, one participant decided to control the volume from the digital interface of the digital music streaming platform while the other participants (e.g., see Figure 5b) were controlling volume through the tangible buttons of the smartphones. These two scenarios revealed the fact that digital interface interaction took more time than the tangible buttons with the help of eye tracking recordings.

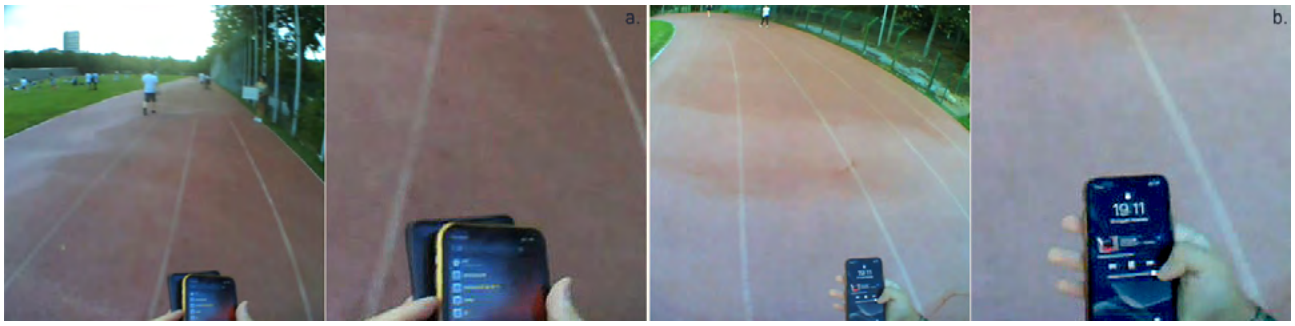

Figure 5. Screenshots from eye-tracking recordings while a participant: a. controlling the volume from the music platform interface; b. turning the volume down from the smartphone interface.

Creating or editing playlists on the move, like running, can be intricate. The reality is that our preferences and moods may change dynamically during the run, making on-the-move adjustments essential. This challenges the notion that this task is better suited for pre-run setup or post-run sessions when the runner can allocate more time and focus. Instead, we argue for the necessity of better-designed interfaces that cater specifically to the dynamic needs of runners, allowing them to seamlessly modify playlists as they go.

Modifying a playlist, such as rearranging songs or adding new ones, can be cumbersome if the interface lacks user-friendly drag-and-drop features. Accordingly, changing the playlist while running emerged as the most difficult command for the participants. Interacting with multiple icons and screens to change the playlist results in participants spending an extended period in this orientation. Another contributing factor to a runner's difficulty in altering their playlist is often the pre-existence of a single, pre-prepared playlist before the run. Consequently, they may have found themselves spending additional time searching for an alternative playlist to switch to as soon as they receive the command.

In summary, the most user-friendly music controls for runners are typically those that demand minimal effort, such as play/pause and volume adjustments. On the other hand, controls involving precise navigation, searching, or playlist management can pose more challenges during a run, necessitating extra attention and potentially distracting from the overall experience. Runners commonly appreciate devices and platforms that strike a balance between functionality and ease of use while on the go.

4.3 Design Suggestions

Based on the research findings, a range of insights, both general and feature-specific, can be proposed for the design of digital and physical interfaces for devices and the music streaming platforms tailored for runners. The design insights from this research have broad applications across disciplines encompassing design, development, health, sports, and design research, benefiting both researchers and practitioners.

The primary outcome of this research was the ranking of the difficulty levels associated with commands executed by runners while running with music. Data collected from the participants' verbalized and numerical evaluations from the field study revealed that changing the playlist ranked as the most challenging command, whereas volume up/down commands were the easiest to execute. In addition to this, design suggestions were offered for both tangible and digital interfaces, aiming to enhance the experience of listening to music while running. These suggestions are based on the insights gained through participant interviews and the eye-tracking recordings during the fieldwork. The design development suggestions can be organized under the following headings.

Intuitive Physical Controls
Elevating the running experience with music involves thinking carefully about how digital and physical interfaces work together in terms of user engagement and overall satisfaction. Central to this enhancement is the incorporation of intuitive physical controls. These controls should feature sizable, tactile buttons strategically positioned to facilitate common functionalities such as play/pause, volume adjustment, and track skipping. The tactile nature of these controls is designed to afford users the ability to manipulate music playback without diverting attention from their running focus.

Voice Commands
Complementing physical controls, the integration of voice command functionality introduces a hands-free dimension to music playback, track selection, and playlist management. The robustness of voice recognition, particularly in acoustically challenging outdoor settings, becomes a critical consideration. Concurrently, the incorporation of gesture controls on touchscreens aligns with contemporary interaction trends. These gestures, designed to be both intuitive and responsive, can be further customized to accommodate individual user preferences.

User-Friendly App Interfaces
In the digital domain, the development of user-friendly app interfaces emerges as a crucial priority. Mobile and smartwatch apps should be carefully designed to facilitate seamless navigation with minimal user input. This involves the provision of large touch targets for key controls and gestures, contributing to an interface characterized by both efficiency and user-friendly design.

Personalization
Playlist management plays a vital role in enhancing the user experience. A streamlined process for creating, editing, and organizing playlists is essential for user convenience, particularly before a run. Moreover, the implementation of automated playlist suggestions, tailored to a runner's preferences and past listening habits during workouts, enhances personalization to a greater extent.

Adaptive Interfaces
The notion of adaptability extends beyond interface design to the performance of the interface itself. Adaptive interfaces, responsive to a runner's pace and movement dynamics, help reduce unintended inputs during high-speed runs. This adaptability is further underscored by customization options, allowing users the ability to adjust interface sensitivity in accordance with individual preferences.

Integration with Health Data
Integration with health and fitness data amplifies the holistic nature of the music–running relationship. By integrating metrics, such as heart rate and GPS information, the design can facilitate the generation of

tempo-synced playlists aligned with the runner's pace. Furthermore, the incorporation of voice feedback on performance metrics, such as distance covered or calories burned, can augment the informational aspect of the running experience.

Social Features
Within the social realm, features enabling interaction and collaboration among users are integral. Incorporating social sharing mechanisms within music applications fosters a sense of community, allowing runners to share achievements and musical tastes. Additionally, tools for discovering new music through social interactions, such as playlist recommendations from peers, contribute to a collaborative and enriching environment.

Feedback Mechanism
Last but not least, a robust feedback mechanism is one of the most important experience improvement strategies. Providing real-time feedback upon reaching specific running milestones, whether they are distance goals or personal records, is crucial for sustaining user motivation. The customization of feedback to be motivational and encouraging fosters a mutually beneficial and positive relationship between the runner and the musical accompaniment, culminating in an enriched running experience.

5. Conclusions

The primary conclusion of this study, derived from semi-structured interviews and eye-tracking data from the fieldwork, is the identification of the most challenging aspects of runners' interactions with both tangible and digital interfaces of their music-listening devices. Changing the playlist was observed as the most time-consuming interaction, which was justified by the fact that there were multiple steps to complete in order to perform this interaction, all performed through the smartphone and digital music listening platform interfaces of. Conversely, the easiest interaction for the participants was increasing/decreasing the volume, largely performed using tangible buttons on their smartphones, explaining its quicker and more straightforward execution. Within the scope of this study on amateur runner experiences, it was discerned that users tend to navigate tangible interfaces faster and more easily than digital ones. Additionally, it was inferred that individuals engaging in outdoor mobile exercises prefer minimal interaction with devices when controlling music.

In addition, design suggestions were informed by the valuable insights shared by the participants during interviews and the eye-tracking recordings. These suggestions aimed to address variations in the digital music listening platforms used by the participants. Rather than suggesting changes or elimination of elements within a specific interface, suggestions were made to improve the interactions between different interfaces considering the overall experience. The primary approach for these design suggestions involved exploring options for multi-sensory interactions. Runners should not only interact through touch and visual feedback, but also through audible and haptic means. Another design suggestion emphasizes user-friendly interfaces for digital music listening platforms, specifically tailored to enhance running experience. This signifies a shift from isolated interface improvements to a holistic approach that considers the entire running experience. Lastly, the integration of social sharing mechanisms into the digital music streaming platforms is proposed to enrich the music listening experience for runners, aligning with the overall design approach.

Incorporating responsive design into music player interfaces for runners can allow adjustments based on activity level, preferences, and environmental conditions. For example, during running, the interface can prioritize essential controls while minimizing distractions for improved usability. It can adapt to user behavior and can dynamically adjust itself to environmental factors like lighting and noise levels, enhancing improved visibility and usability in different conditions. This flexibility, tailored to each runner's needs and context, contributes to a smooth and enjoyable experience. Our research findings have highlighted the intricate relationship between running and music, emphasizing the need for carefully tailored interaction features in devices and music platforms for runners. Effortless access to music controls not only enhances the overall running experience but also reflects a user-centric design approach, ensuring that the joy of running with

music remains undisturbed by cumbersome interfaces. By addressing the specific requirements of active users, music playing devices and streaming platforms can provide a seamless and enjoyable experience not only for runners but also for individuals engaged in other physical activities.

KEYWORDS | IMMERSIVE EXHIBITIONS, EXHIBITION DESIGN, GIS, DATA VISUALIZATION

ABSTRACT | Currently, exhibitions known as “immersive experiences” constitute an important part of present-day media transformation and have become a major development direction in the field of exhibitions. Immersive displays within the realm of exhibition design entail two distinct requirements: firstly, they necessitate diverse stimuli to complement the artwork itself, and secondly, the exhibitionary complex and its affiliated institutions have to adapt and emancipate themselves from conventional exhibition methods. Based on this premise, the authors explain how the transformation of physical space in immersive exhibitions engenders a new relationship between viewers, art and the exhibition setting through the example of their new media artwork Longitude and Latitude. Shown in the contemporary art exhibition Infinity: The Sequence from Known to Unknown (2021-2022) in the Suzhou West Museum, the artwork utilizes HOUDINI’s point cloud technology and an enhanced cellular automata algorithm to visualize geographic data.
This project exemplifies the three stages of data visualization: data transformation - content transformation – and spatial transformation, which includes the output of data into an immersive spatial narrative within the exhibition space. The expansion of the exhibition space through immersive technologies aims to visualize geographic data and simulate the past and future land use in Suzhou for a better understanding of the city’s development. Our design approach aims to create specific modes of perception that affect the interaction between visitors, exhibition architecture, and narrative design.

1. Introduction

In both commercial and museum settings, the use of contemporary immersive media technology has become an important development in the field of exhibitions. These exhibitions, often referred to as "immersive experiences," employ new media forms such as virtual reality (VR), augmented reality (AR), and 3D mapping, leading to the facilitation of immersive communication and experiences, and they constitute a significant part of the broader media transformation.

Immersive exhibitions can emancipate from traditional gallery displays as they offer visitors a distinct mode of engagement. These exhibitions enable visitors to freely explore and interact with their surroundings, resulting in more captivating encounters. Visitors are empowered with autonomy through bodily engagement and spatial positioning, allowing them to plan their own routes and physically navigate through the exhibition space, thereby obtaining diverse and personalized visual experiences. These exhibitions provide multifaceted immersive experiences while also exploring curatorial strategies that create illusions and enhance engagement.

In his research on the digitalization of museums, Ross Parry has previously traced the process of compatibility between museums and digital media. This process includes the digitization of archival systems, the presence of digital objects in exhibition spaces, interactive displays, and the virtualization of museum visits through online resources. These changes have led to the "recoding" of museums, shifting from an emphasis on "object-oriented, conservative structures" to "experience-oriented, user-driven, multi-channel media systems" (Parry, 2007). This recoding encompasses a user-centric, media-driven system that reflects the evolving nature of cultural institutions in response to the digital age.

Overall, the integration of digital media in museums has transformed their operations and engagement strategies, allowing for new forms of interpretation, interaction, and accessibility, signifying a paradigm shift in the curatorial guiding principles of immersive exhibition design. This immersive shift has affected the perspective of visitors, particularly the dynamic relationship between visitors and exhibited artworks. This transformation can be examined from the perspectives of presentation, information dissemination, and aesthetic experience.

Nevertheless, physical architectural dimensions do not constrain spatial narratives, neither does the combination of immersive media technology completely subvert previous modes of exhibiting. Instead, conscious design choices during the art creation and exhibition design process have the potential to complement and extend spatial narratives with the help of new media technologies. Therefore, within immersive exhibitions, physical exhibition settings have the potential to seamlessly integrate with the artwork, offering visitors a holistic and immersive experience.

Based on this premise, the authors explain how the transformation of physical space in immersive exhibitions puts forward this experience-based relationship between viewers, art and the exhibition setting through the example of their new media artwork *Longitude and Latitude* (Zhang, 2022). Shown in the contemporary art exhibition *Infinity: The Sequence from Known to Unknown* (2021-2022) in the Suzhou West Museum, the artwork utilizes HOUDINI's point cloud technology and an enhanced cellular automata algorithm to visualize geographic data. In this case study, the expansion of the exhibition space through immersive technologies aims to visualize geographic data and simulate the past and future land use in Suzhou for a better understanding of the city's development without relying on displaying physical artefacts, embodying an “object-less” immersive experience.

This project exemplifies the three stages of data visualization: data transformation - content transformation – and spatial transformation, which includes the output of data into an immersive spatial narrative within the exhibition space. This approach does not aim to substitute the physical material of exhibits but rather creates specific modes of perception that affect the interaction between visitors, exhibition architecture, and narrative design. This paper aims to compare and analyze immersive

exhibitions from the standpoint of the interactions between the audience, the exhibition spaces, and the artwork. The analysis will be conducted by examining the digital artwork and its display in the context of the "experiential complex," (Hall, 2006), in which visitors no longer remain distant from artworks due to their representational nature, but are fully immersed in the theme of the exhibition.

2. Methodology

The exhibition *Infinity: The Sequence from Known to Unknown* (September 25, 2021, to February 16, 2022) was conceptualized as the first major exhibition of modern art in the Suzhou Museum West, officially opened in September 2021. Designed with a visitor-oriented interior architecture located in a prominent area at Shishan Square, the museum building itself serves as a cultural landmark of Suzhou, holding both permanent and temporary exhibitions that highlight the tangible and intangible heritage of the city (Chen, 2021).

Among the exhibition, the new media artwork *Longitude and Latitude* was created by Prof. Zhigang Wang's team at the Department for Information Art & Design at Tsinghua University, which includes Yuan Zhang, Zichen Xi, Shunni Feng, Ruitao Guo, and a collaboration with ImageSky Remote Sensing Technology Co. The artwork consists of a video display lasting two and a half minutes, displayed within a separate room within the museum. The exhibition design consists of a large-scale screen that projects the video in a loop, and two mirror installations that reflect the image content.

The concept of *Longitude and Latitude* is based on tangible and intangible heritage representing Suzhou's culture and history. The design is driven by data visualization and symbolizes the local customs of Suzhou, the characteristics of Jiangnan culture, and the city's past and future through geographic information data. By selecting the material properties of silk and water as elements that characterize the city's history and culture, the artwork explores the threads of urban development spanning thousands of years.

The image sequences in *Longitude and Latitude* use the motifs of silk and water by displaying horizontal and vertical silk threads as abstractions that correspond to the latitudinal and longitudinal coordinates of rivers, lakes, and commercial waterways on Suzhou's map. On the one hand, the concept of *water* embodies elements of the cityscape following the changes of time. Suzhou's urban development has been shaped the transformative forces of water bodies such as rivers, oceans, and lakes, highlighting the relation between urban growth and changes in the surrounding bodies of water. The water-based design in the artwork thus presents a macroscopic view of urban development, serving as an abstraction for the city's history and culture.

On the other hand, *Suzhou Silk* holds immense cultural value as it represents Suzhou's artisanry. The *Archives of Suzhou Silk from Modern and Contemporary Times,* which document the silk industry and silk production methods, have been registered as a "Memory of the World" by UNESCO and ICDH, establishing Suzhou as a prominent hub and leading city for China's silk-weaving techniques (ICDH, 2017).

However, the scope of *Longitude and Latitude* extends beyond the content regarding Suzhou's cityscape and cultural heritage. A crucial aspect of our artwork lies in its immersive display method. Our aim is to explore the transformation of physical space within the city, showcased through an immersive exhibition setting that creates a novel dynamic between the audience, the absence of physical objects, and the artwork within the limited physical space of the exhibition. As a result, the creation process of the artwork follows a three-stage artistic transformation model, encompassing not only the image sequence but also the innovative display approach (Figure1):

1. Data Transformation – Geographic data collection using historical documents and remote sensing technology.
2. Visual Transformation – Video production using Houdini, Blender, Procreate, Adobe AE, PS, AI and PR.
3. Spatial Transformation – Exhibition space production using Kinect, Resolume Arena Projector, Mirror Material, etc.

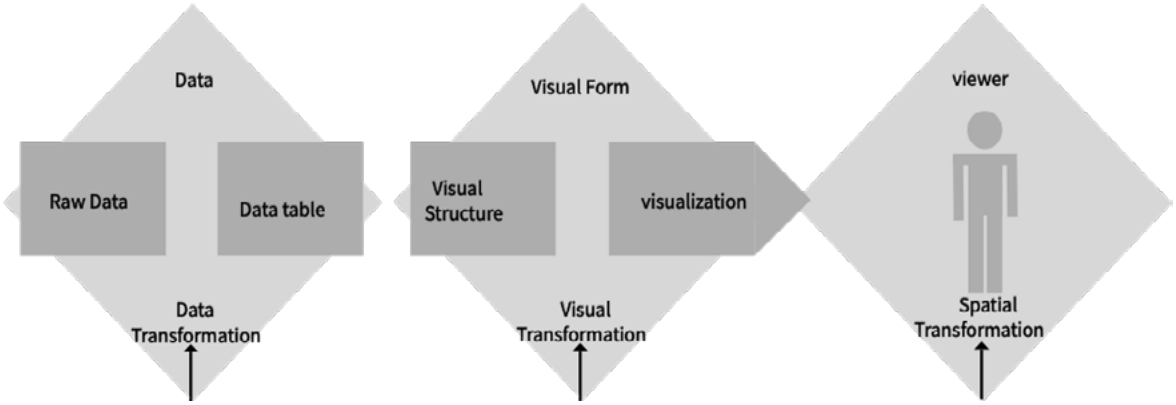

Figure 1. Three-stage artistic transformation model (© Yuan Zhang).

Our production process thus involved a data collection process of physical historical documents and remote sensing maps, followed by the organization, analysis, and transformation of the data into 2D vector graphics using manual and algorithmic techniques, and the visualization of the data through multi-dimensional methods, ultimately creating a comprehensive video format. The last step involves the spatial transformation of the exhibition venue.

2.1 Data Transformation

The process of data visualization allows for the transformation of complex datasets into visually compelling representations. In this context, the creation of *Longitude and Latitude* involved geographical data, processed in a multi-step approach, which was inspired by the information visualization model proposed by Card et al (Card et. Al, 1999). Our data transformation process is comprised of four steps (Figure 2), aimed at processing and transforming geographical data into visually meaningful 2D vector graphics for further video production:

1. Data collection;
2. Collation, analysis, and extraction;
3. Transformation into vector mapping through the manual and algorithmic generation;
4. Visualization.

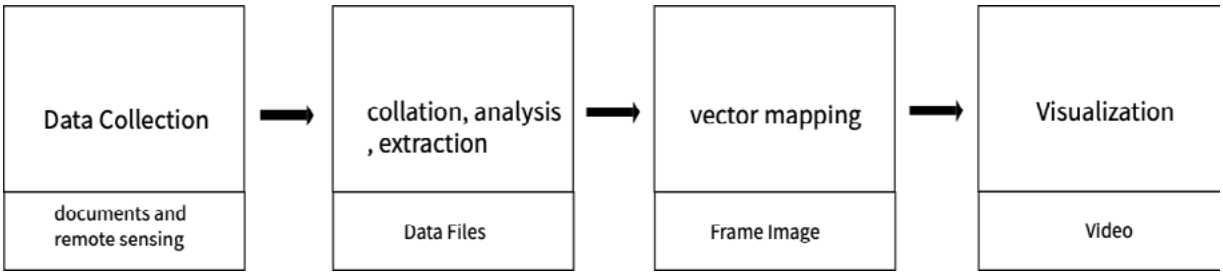

Figure 2. The Process of Data Transformation (© Yuan Zhang).

During the initial step, we collected geographic data derived from two primary sources – physical historical documents and remote sensing maps of Suzhou. We obtained the latter through a collaborative effort with ImageSky Remote Sensing Technology Co.

The physical historical documents serve to contextualize the development of Suzhou's landscape from ancient times to the present day, providing insights into the changes caused by rivers, agriculture, commerce, and various other societal and natural factors. In contrast, the remote sensing maps focus on the effects of specific economic and political decision-making, such as the establishment of water systems, scenic spots, national railroads, subways, green areas, and the impacts of congestion from 1984 to 2021. We recorded and saved information derived from both types of sources in the format of videos, pictures, and text for further usage in the subsequent stages of the data transformation process.

The second step of the data transformation stage involves the tasks of organizing, analyzing, and extracting geographical data, which includes the selection of appropriate technologies for different data formats, the transformation into desired formats, and the subsequent classification, compression, and decompression. We employed ArcGIS to transform the main initial remote sensing data and then used the built-in script module of Houdini to classify the land types in Suzhou based on the obtained information.

The third step involves the conversion of the extracted information into 2D vector graphics through a combination of manual and algorithmic generation techniques. The manual approach specifically focuses on utilizing information from archaeological historical materials and physical historical maps to create vector graphics. These graphics relate to several aspects of Suzhou's history, including water bodies, agriculture, commerce, and war, spanning from the Qin dynasty (221 BCE-206 BCE) to the Qing dynasty (1644 CE-1912 CE). For example, we manually extracted the topography in the case of a 1229 Song dynasty (960 CE-1279 CE) Suzhou city map, known as the *Pingjiang* Map, which remains as the largest surviving ancient city map of China (Zhang, 2013). Our effort included capturing details on Suzhou's *Water Network Change Map*, *Lake Boundary Line Change Map*, *Location Map of Human Settlements*, etc., in addition to vectorizing canals, moats, city rivers, lakes, ponds, bays, and other water-based entities that affected urban freight and trade exchanges of Suzhou's ancient commerce.

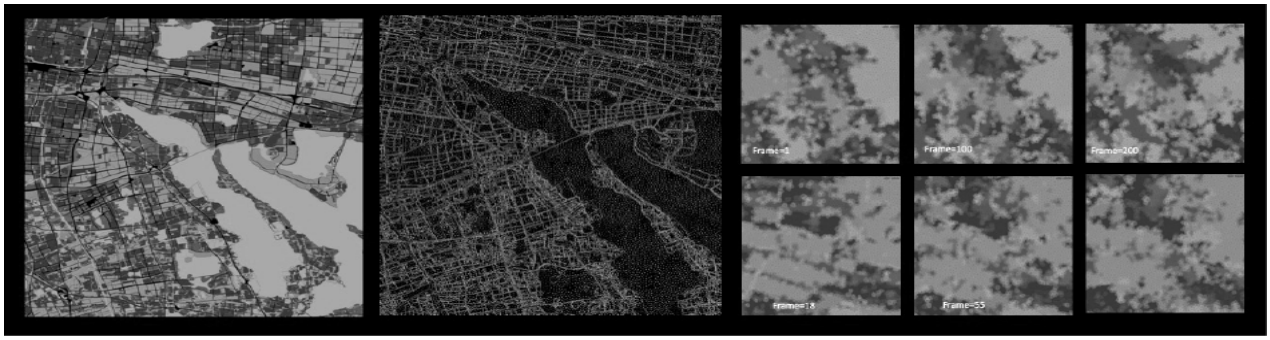

Figure 3. Algorithm Generation Process (© Zichen Xi).

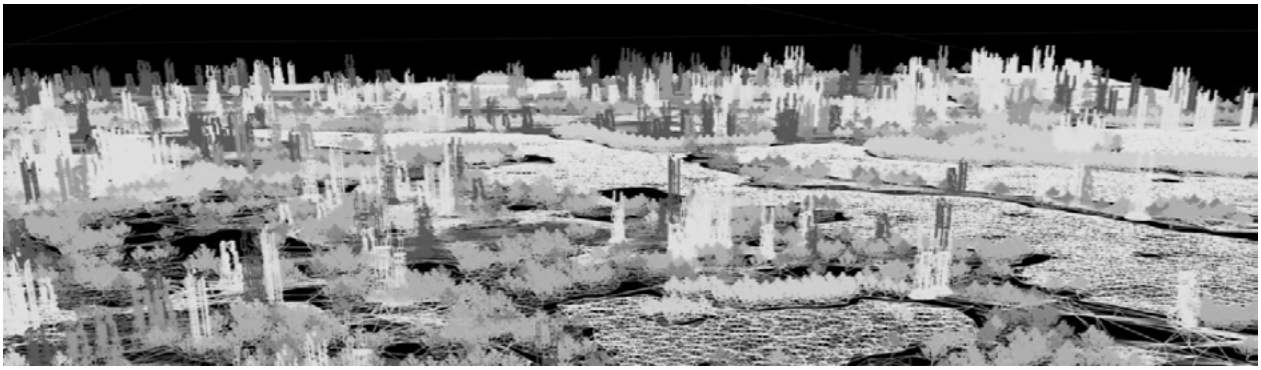

Figure 4. Algorithm generation process (© Zichen Xi).

In contrast, we employed an algorithm generation method to analyze the remote sensing satellite data provided by ImageSky Remote Sensing Technology. The quantity and data accuracy from these maps allowed for the automatic transformation of data into a two-dimensional vector graphic (Fig. 3), classified and graded according to the national Chinese land-use standard (Chen and Zhou, 2007). These encompass three categories of human-made land, vegetated land, and water bodies (Fig. 4). The utilization of Cellular Automata Algorithms enables a simulation the future trend of changes in natural vegetation due to human modification over time.

Finally, the fourth step consists of the visualization of these data points into a video format. We use multi-dimensional data visualization methods for the geographic data from the maps (Shneiderman, 1996), which include the parallel coordinate system method (Inselberg, 1985), RADVIZ method (Kandogan, 2001), scatter plot matrix method (Craig and Kennedy, 2003), and 2D icon-based visualization for historical geographic data. Here, data from different maps correspond to variations of icons, with variables such as "human settlement points", "water network lines", " Lake Boundary Lines", etc., that are represented by size, radius, location and color (Fig. 5). For the visualization of modern geo-data, 3D buildings are generated. The height and number of these buildings is based on records of changing land prices and population density. The 2D vector graphics from the previous step are used as the reference points for each building unit, supplemented by artistic embellishments such as particle effects and luminous effects.

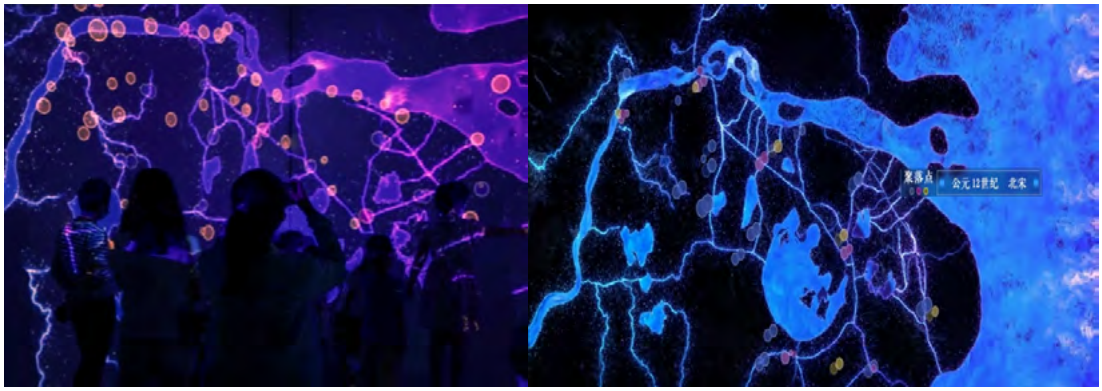

Figure 5. Exhibition Display. “Positive” correlation between the radius and number of human settlements-dots (© Yuan Zhang).

2.2 Visual Transformation

The visual output of the artwork involves transforming the geographical data into a video format, with water and silk serving as recurring motifs. We employed various multi-dimensional visualization softwares, including Houdini, Blender, Procreate, Adobe AE, PS, AI and PR, to showcase the graphics that resulted from the previous step. By relying on water as a narrative design element, the image sequences relay information on the city's development through a temporal division of four chronological sections:

- Water and continent - the formation of impact plains;
- Water and agriculture - the transformation of the natural environment;
- Water and commerce - prosperous urban development;
- Information Future - a new future blueprint for innovative Suzhou.

The video commences with an animation of the formation of the middle and lower Yangtze River plains through a visualization of the interactive nature between water and land (Fig. 6). It progresses to showcase the emergence of human civilization, represented by latitudinal and longitudinal locations of fire relics, early human rice relics, and the waterway irrigation. This information relay points out the close relationship between water, environmental and agricultural change, the development of human society, as well as the abundance of these water resources and its role in managing of the development of agriculture, fisheries and hunting.

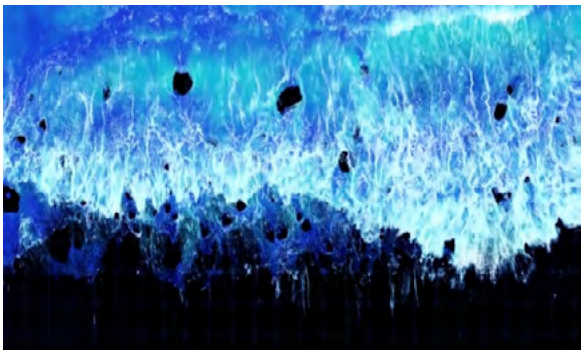

Figure 7. Lower Yangtze River Visualization (© Ruitao Guo).

Figure 8. Lower Yangtze River and Tai Lake Visualization (© Shunni Feng).

The relationship between water and commerce is based on the information collected from the *Pingjiang map* and other historical materials. Using artistic processing to interpret the cityscape of ancient Suzhou, we restored the appearance of the Suzhou night market during the first peak of the city's development in the Song Dynasty (Fig. 9). We used particle effects to accentuate the movement patterns of the busy crowd within the night market, the spatial distribution of commercial districts and commercial waterways, as well as the positionings of the main road network and other infrastructure elements. This particular video segment displays Suzhou's distinctive "water town" feature through a double checkerboard pattern that represents the interplay between land and water.

The final segment of the video uses the city's historical patterns of water, land distribution and architecture to interpret Suzhou's past and future urban development. In the final moments, the video concludes by revisiting the geographic coordinates (longitude: 120.54620735298157, latitude: 31.293915174794172) of Suzhou Museum West, providing viewers with a tangible reference point to comprehend their current position in relation to the potential future urban landscape of Suzhou (Fig. 10). This serves to establish a sense of connection between the present reality and the envisioned future, allowing viewers to envision the city's prospective transformations.

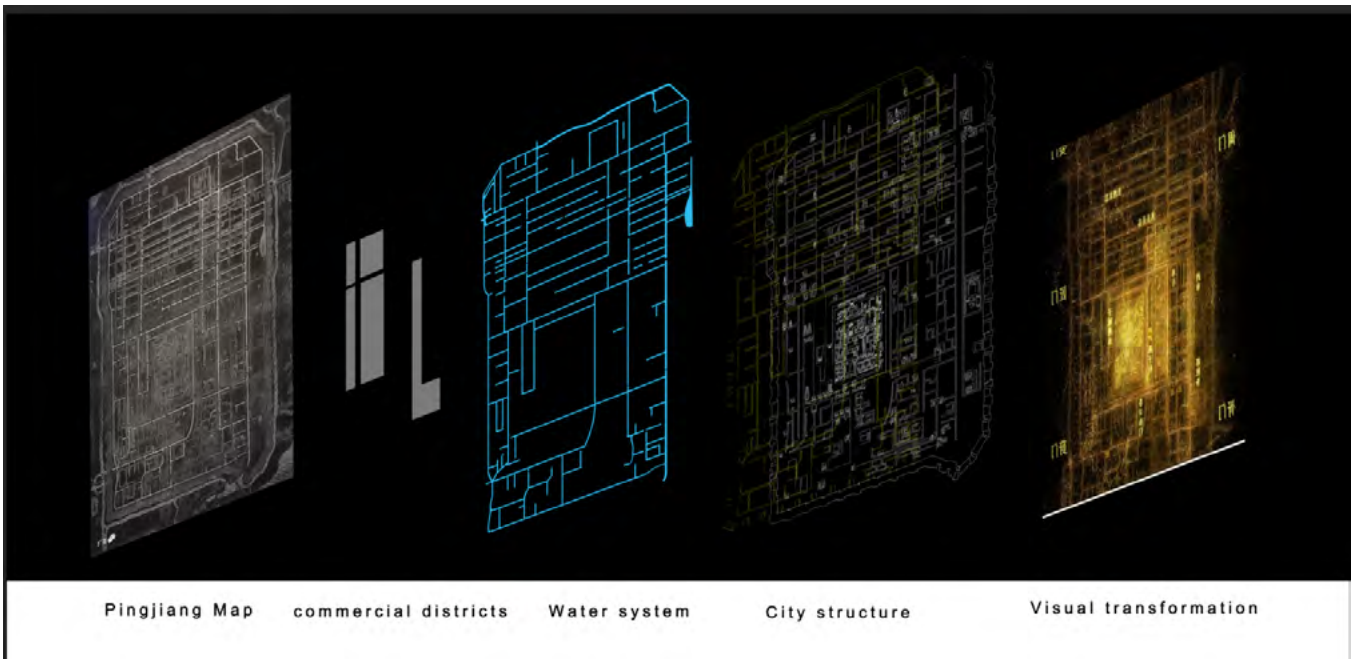

Figure 9. Rendering the Night Market of Suzhou during the Song Dynasty (© Yuan Zhang).

Figure 10. The Future Urban Landscape of Suzhou (© Zichen Xi).

2.3 Spatial Transformation

Longitude and Latitude completes the final transformation of data-content-space (Figs. 11, 12, 13) by expanding the exhibition space through video projection and specular reflection, creating an immersive experience.

Our approach to designing the exhibition display for *Longitude and Latitude* aims to substitute conventional exhibition methods of showcasing geographical information through material objects. Instead, we utilized new media technology to present the narrative of cultural history in a digital dimension within a physical space. By doing so, we intended to achieve a quantitative representation of extensive geographical data and bridge ancient history and intangible future development.
By combining physical space, virtual space, video content, and mirror reflection, the artwork attempts to break the spatial limitations of the physical exhibition environment and expand the scale of the entire artwork itself in the space, where the audience is able to envision geographic information from all angles, both from the physical space to get a wrap-around sensory experience, and from the virtual space to gain knowledge on Suzhou from ancient times to the present day. In addition to the physical and temporal location of the artwork, the virtual space serves to let visitors perceive various layers of immersion, exploring the transformative aspects of the city through a transformation of the exhibition space itself. This virtual realm – established through video projection and extended through mirror installations – supports the physical exhibition space by transcending the limitations of "material presence" and instead offering an experience imbued with an "auratic" sensation, which goes beyond the interaction between viewers and physical objects.

Our immersive exhibition design thus explores the fluidity of integrating the exhibition space with the artwork to provide visitors with a holistic viewing experience.

3. Implications

We aimed to create *Longitude and Latitude* as an illustration of the departure from traditional exhibition methods by establishing an immersive environment within the context of the Suzhou West Museum. By reconstructing the past of the city, the primary focus during the design process involves translating data gained from ancient and remote sensing maps into a format that could understood and absorbed by the audience without the presence of original artefacts. Through the integration of the limited physical exhibition space and immersive display techniques, the inherent quantity of data can be showcased through the expansion of the physical space through the different layers of data transformation.

As a more recent evolvement in the history of exhibition practices, Martin Hall interprets this type of immersive exhibition mode brought about by new media as an "experiential complex" (Hall, 2006). Hall bases this model on the ideas of Joseph Pine and James Gilmore, who argue that "experience" has unique qualities compared to "commodities" and "services" – while commodities and services are external to individuals, experiences have the ability to touch people's inner selves and profoundly impact them (Pine and Gilmore, 2020).

While Pine and Gilmore argue that immersive experiences touch upon four domains – entertainment, education, escapism, and aesthetics – Hall provides further insights by emphasizing that education requires active engagement, while escapism necessitates immersion in the experience rather than passive observation associated with entertainment. Within this particular context, the gallery space assumes the role of an educational conduit, facilitating an environment that encourages active engagement and deep absorption. Consequently, it serves as an extension of the traditional method of exhibition display.
Our immersive approach to *Longitude and Latitude* takes two essential features of immersive exhibitions into consideration: the absence of material objects and the expansion of physical space.

In fact, one major concern regarding immersive exhibitions is the emphasis on "aesthetic adaptation" rather than "authentic presentation" (Huang, 2023). This issue arises when comparing the traditional exhibition complexes filled with "real objects," with the often "object-less" immersive experiences. Linking this viewpoint to Walter Benjamin's notion of the decline of traditional "aura-based art" and the rise of modern "reproductive art" (Benjamin, 2018), we can observe a shift in the aesthetic experience of spectators — from a state of "focused" attention to one of distraction. This transformation is equally applicable to immersive exhibitions, which can be seen as a contemporary form of art reproduction. According to Kim West, this phenomenon not only enables reproduction but also allows for the mobility, recontextualization, comparison, and combination of art (West, 2017)—a notion reminiscent of André Malraux's "Imaginary Museum," in which art "loses its object quality" and is "confined to a material experience" (Grasskamp, 2014). Malraux considers the "Imaginary Museum" as an "auratic museum" rather than a substitute for physical museums. The key element of this type of experience is the exhibition design itself. According to Pine and Gilmore, this "experience design is determined not only by the exhibit's instructions on how to use the space but also by the absence of functions that adhere to established uses" (Pine and Gilmore, 2020).

We thus aimed to transform the physical exhibition space by offering an immersive encounter that effectively embodies the distinctive qualities of Malraux's concept of the "auratic museum," all the while remaining firmly grounded in the physical realm. The amalgamation and recontextualization of historical data in its present setting enable immersive experiences to deliver the same range of entertainment, education, escapism, and aesthetics as emphasized by Pine and Gilmore. The physical exhibition space itself assumes a pivotal role in effectively conveying these messages – and further indicates that immersive exhibitions may not only be seen as a "transformation" of tradition but rather an expansion and modern adaption of the exhibitionary complex as previously described by Tony Bennett (Bennett, 2019).

In immersive exhibitions, the relationship between the audience and the artwork depends on the viewer's interpretation of the presented objects. According to John Hannigan, immersive reconstructions are not

intended to make visitors believe they are experiencing a real environment, on the contrary, part of the enjoyment comes from being aware of the immersive technology and admiring the simulation of realism in animation. Hannigan describes the pleasure derived from a "suspension of disbelief" from the paradoxical coexistence of recognizing a technological illusion while simultaneously experiencing an authentic sense of immersion through the interplay of exhibition design, space and the artwork itself (Hannigan, 2005).
As a result, the exhibition space is no longer merely a vessel for objects but an integral part of the art itself. In fact, the physical architecture of the exhibition room does not serve as a limiter for the exhibition experience. Ross Parry and Andrew Sawyer point out that architectural space “frees us from the limitations of the web page”. By merging the physical space with the virtual, a new spatial narrative produces a new kind of relationship between art, space, and people (Parry and Sawyer, 2005).

Guided by the above-mentioned principle that immersive media regards the exhibition space as an intrinsic component of the artwork, our design for *Longitude and Latitude* involved spatial configurations achieved by deliberately selecting and arranging various display elements. These included the strategic placement of video projection, the incorporation of reflective surfaces, sound design, and lighting techniques.

Longitude and Latitude thus intends to provide an alternative sensory experience for interpreting the history and future of a city by interconnecting ancient data with modern technology through an object-less display, forming a chronology of the city’s temporal dimensions without relying on a preprogrammed, “ritualistic” museum route (Duncan and Wallach, 1980).

The final, spatial transformation of our project thus allows visitors to experience the development of Suzhou through a “Spatial Narrative” that uses the scale and volume of space rather than the spatial sequences of exhibition settings to produce a narrative.

4. Conclusion

Within the context of museums, immersive experiences have the potential to fundamentally change the interaction between visitors, artworks, and exhibition spaces. Everett Ellin, referring to new electronic technologies as the "dominant medium of our time", suggests that these technologies teach people to interpret the world through multiple simultaneous sensory experiences (Ellin, 1967). On the one hand, this requires various stimuli to complement the artworks themselves, and on the other hand, it demands that museums break away from traditional exhibition models to enhance the visitor experience. Ellin believes that the emergence of these technologies creates an environment of "all-at-onceness" that enables individuals to constantly engage with one another and experience multiple forms of communication, ultimately altering our perception and modes of thinking, and giving rise to a new mode of subjectivity. The emerging immersive technologies not only complement but also enhance traditional practices by providing additional dimensions for exhibition experiences.

By triggering the audience's imagination and utilizing media and technology, exhibition venues can create immersive experiences that go beyond observation, allowing visitors to actively engage, escape from reality, and appreciate aesthetics. The interpretation and involvement in immersive exhibitions ultimately lie in the agency of individual viewers, and the level of immersion depends on the curator's and artists' ability to create suspense and the art itself.

Through *Longitude and Latitude*, we aimed to achieve this effect by transforming the historical display of the cityscape, as well as the exhibition space itself into a coherent spatial narrative as an integral part of the artwork. During the design process of the artwork, the three modes of transformation – data transformation, visualization, and spatial transformation – serve to provide the audience with a multi-layered immersive experience to educate on the city’s historical and future development. The transformative aspects of our design aim to establish a display system that uses new media technology to allow the creation of spatial narratives that go beyond the limitations of physical objects, enhancing the viewer's experience and creating a sense of collective immersion.

About the Authors:

Angela Chulei Tang, a design researcher, who explores the re-contextualization of art and architecture through digital technologies and spatial narratives. Her research focuses on theoretical frameworks on local and global scales, as well as transcultural perspectives regarding global art, heritage protection, and new media technologies.

Yuan Zhang, an interdisciplinary visual designer and cross-media narrator, specializes in immersive new media arts, performing arts, and digital expressions of traditional culture. Her notable achievements include design work for major events and contributions to projects in interior design, film, and games, receiving awards and recognition for her contributions in these fields.

Wang Zhigang, a professor and doctoral supervisor at the Department of Art & Design at Tsinghua University, specializes in cross-disciplinary integration of animation, image, interactive technology, and stage performance art. His notable achievements include several multimedia designs for major national and international events and performances, receiving awards for innovation in art and science.

Acknowledgements: We thank Image Sky Remote Sensing Technology Ltd and E-GO Computer Graphics Co., Ltd for supporting the production of the Longitude and Latitude. Our thanks go to the China Association for Science and Technology, who funded and realized the project, the Suzhou West Museum for providing exposure and the exhibition space, and Zichen Xi, Shunni Feng and Ruitao Guo for taking part in the project and creating of the images included in this paper.

KEYWORDS | EXTENDED REALITY (XR), WEB 4.0, USABILITY TESTING, HEURISTIC EVALUATION

ABSTRACT | The theoretical section of the paper outlines the progression of the Internet from the Web 1.0 era to the speculative notion of Web 4.0. The latter is referred to as the symbiotic web, wherein the prevailing solutions such as Artificial Intelligence (AI), Internet of Things (IoT), Virtual Reality (VR) and Augmented Reality (AR) developments serve as the framework for advancements that establish a harmonious connection between the user and the software product. Web 4.0 is expected to demonstrate unique characteristics, specifically proactive, content-exploring, self-learning, collaborative, and content-generating solutions (such as extended reality (XR)). XR is an umbrella term derived from the VR-AR continuum, and as an emerging concept, it can revolutionise how people perceive and engage with their environment. The paper evaluates a prototype XR software product designed for fashion model agencies through empirical and analytical usability studies. The research aims to thoroughly understand the user requirements for forthcoming immersive environments, encompassing insights from potential users and experts in user experience (UX) design. To achieve this goal, we conducted a Rapid Iterative Testing and Evaluation (RITE) usability study with a sample of potential users (n=13). We assessed the system's overall usability and gathered subjective feedback by administering a System Usability Scale (SUS) questionnaire and conducting a follow-up interview. Besides that, a usability inspection method was applied, where UX specialists (n=6) were engaged within the framework of heuristic evaluation. Similarly, in this instance, the heuristic evaluation was accompanied by a subsequent interview, in which the experts imparted their subjective experiences and professional insights to us. The user-centred studies have resulted in diverse forms of feedback. The RITE test identified several minor usability issues, such as the absence of software affordances and familiar interactions. On the other hand, the heuristic test has highlighted suggestions for long-term improvements, primarily focusing on the ergonomic design of the XR space across various sub-dimensions. We systematically compare and contrast usability observations from empirical and analytical studies, demonstrating the practical value of applying these methodologies in developing XR software products. Consequently, this paper provides a comprehensive analysis of the results derived from the different types of usability studies that could be useful for creating and developing future immersive spaces.

1. Introduction

Information technology (IT) has rapidly advanced, breaking barriers of time and space and enabling limitless communication. This transformation affects our lives, including work, leisure, thoughts, actions, and related media consumption or software usage (He et al., 2021; Megyeri & Szabó, 2024).

The Internet is the central force of today's digital revolution, acting as a powerful and unstoppable network that connects people across borders and time zones, serving as a worldwide hub for communication, broadcasts, and information sharing. It has evolved from a simple information-sharing tool to a dynamic social interface connecting individuals across changing physical and virtual environments (Tarnoff, 2022).

The evolution of the internet has been remarkable, advancing from the static nature of Web 1.0 to the promising potential of the upcoming Web 4.0 through significant progress. Every advancement has redefined software user interfaces, expanding the limits of what can be achieved in the digital domain (Aghaei et al., 2012).

The continuous evolution of information technology (IT) across the successive epochs of Web 1.0, Web 2.0, and Web 3.0 has profoundly influenced different software's user experience (UX). The transformations of actual UX trends have been driven by a gamut of technological innovations (e.g., radio frequency identification (RFID), mobile technology, virtual and augmented reality (VR/AR) devices, and artificial intelligence (AI)). Such advancements have heralded the arrival of novel and pioneering software across diverse industrial sectors (Khaleel Ibrahim, 2021).

The current path of advancement in IT suggests that several noticeable trends are expected to dominate the latest developments in the software market. Among these trends are the burgeoning domains of big data analytics, machine-to-machine (M2M) communication, cloud computing infrastructures, a variety of AI-driven products, and the burgeoning arena of extended reality (XR) innovations (Hendler, 2009). XR solutions combine augmented reality (AR), virtual reality (VR), and mixed reality (MR) to improve our interactions with the internet and the environment (Bharadiya, 2023).

These developments increasingly constitute integral facets of cutting-edge IT initiatives that contribute to the emergence of the fourth-generation Internet era, Web 4.0. Web 4.0 symbolises an envisaged frontier wherein the fusion between cyberspace and the tangible realm undergoes further augmentation. With the support of numerous emerging IT solutions, this synergistic convergence is ready to give users more customised, intelligent, and immersive experiences, offering designers new UX challenges and opportunities (Pfeiffer et al., 2016).

This paper presents a user-centred approach employed to enhance XR software pertaining to Web 4.0 by comprehending user and UX experts' requirements and insights.

2. Theoretical Background

2.1 From Static Web to Metaverse

Tim Berners-Lee conceptualised the World Wide Web in 1989 as a continuously developing system for organising information (Machado et al., 2019). In the past thirty years, the Internet has evolved significantly, progressing through different stages known as Web 1.0, Web 2.0, and Web 3.0, with the first signs of Web 4.0 currently in progress. Various eras can be distinguished by unique characteristics that have impacted the UX of the associated software (Eftekhari et al., 2011; Hung et al., 2010; Khaleel Ibrahim, 2021).

In the Web 1.0 era (1989-2004), known as the cognition web, the online space resembled a static, read-only environment. Information dissemination dominated, and user interaction was limited, marked by one-way

information flows. Developers wielded significant influence on the design of webpages, focusing on the logical structure and visual meaning, thus creating a cohesive UX (Benford et al., 2009; Choudhury, 2014; Fleming & Koman, 1998).

Transitioning into Web 2.0 from 2004, dubbed the communication web, user participation became the focal point. Coined as the read-write web, this phase facilitated user-generated content through social networking, blogging, and interactive web applications. Web 2.0 spurred advancements in responsive design and dynamic content, enhancing user interactivity and shaping a more engaging, multi-model UX (Law & Van Schaik, 2010; Pranay & Chhetri, 2015). Web 3.0, the Web of Collaboration, was introduced in 2013 and inspired by John Markoff's vision in 2006. The fundamental concept of executive or intelligent web involves improving the ability to understand and process information effectively. Machine-readable data is integrated with metadata to allow software to interpret and analyse web content, resulting in an intelligent and contextual UX. This evolution aimed to enhance machine systems' ability to understand data and aid in decision-making, thereby enhancing the creation of immersive software (Hiremath & Kenchakkanavar, 2016).

The rise of the Web of Integration (Web 4.0) signifies a new paradigm in the IT sector, marked by the integration of various models, technologies, and social interactions. This new version of the internet represents a significant departure from previous versions, introducing a more extensive and interconnected structure. Web 4.0 is a vision of the internet that involves increased personalisation and contextual awareness. The discussed idea envisions a seamless integration of physical and digital realms, where interconnected devices, sophisticated analytics, and intelligent algorithms collaborate to offer customised and intuitive metaverse services (Almeida, 2017).

The metaverse is a concept associated with Web 4.0, representing a globally interconnected virtual 3D environment accessed through the internet, enabling individuals from different locations to engage in shared social experiences. A metaverse integrates the physical and digital realms, allowing users to engage with virtual content in their surroundings. Digital information and virtual objects are tied to particular physical locations, enabling users to access and engage with them in real-world situations (Pangilinan et al., 2019).

For example, utilising XR technologies and incorporating intelligent algorithms (e.g. AI) in a virtual setting can provide consumers with immersive and realistic experiences (Ahuja et al., 2023). It allows digital content to be superimposed onto the real world, creating immersive experiences and new opportunities for communication, collaboration, and information access. Users can navigate and engage with digital content in real time in their actual surroundings, allowing interactive UX in fields like gaming, education, design, and retail (Kuhn & Ballatore, 2015).

2.2 Definition of Extended Reality (XR)

Milgram & Kishino (1994) introduced a fundamental visual representation to demonstrate the range of immersive experiences, encompassing the concept of XR (Figure 1). The AR-VR continuum, illustrated in their diagram, provides an elementary basis for comprehending the different levels of reality-virtuality integration. The virtuality continuum represents a range of actual and virtual environments at opposite extremes (Ribeiro et al., 2021).

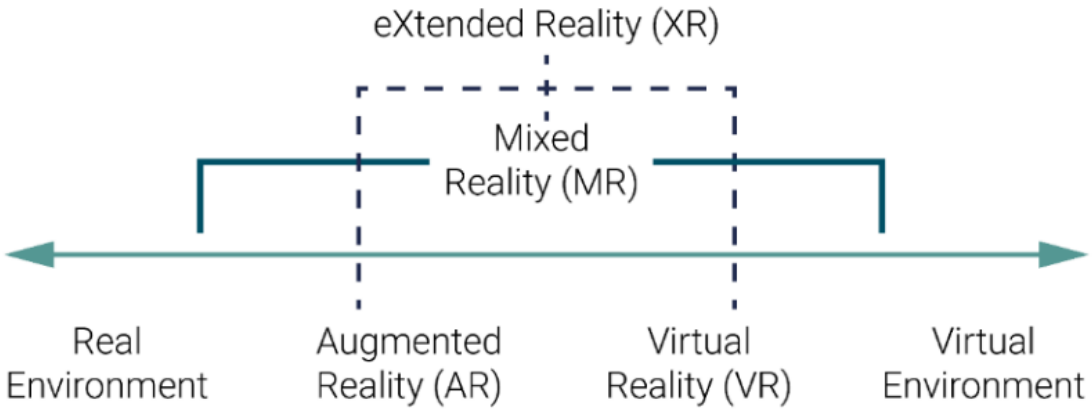

Figure 1. XR adaptation of Milgram and Kishino's virtuality continuum.

AR has a historical lineage dating back to the 1950s; nevertheless, the term gained prominence primarily in the 1990s (Berryman, 2012). AR enhances the user's perception of the environment by superimposing digital information, focusing on a more realistic experience. In subsequent years, AR has undergone multifaceted characterisations, with its central essence commonly construed as a dynamic and real-time amalgamation of digital information and the physical environment (Billinghurst et al., 2015; Javornik, 2016). The evolving nature of AR's conceptualisation underscores its capacity to seamlessly integrate digital content with the perceptible world, indicative of its continual evolution as an interdisciplinary field bridging computer science and human-computer interaction (Fjeld, 2004).

Since World War II, the military has utilised simulators to train combat pilots. The Link Trainer application, used for pilot training before World War II, was one of the earliest instances of a technology similar to modern VR (Jeon, 2015). Virtual reality (VR) encompasses an extensive collection of perceptual experiences generated via the application of various technological devices (Boas, 2013). VR leans towards the virtual reality end, completely involving humans in computer-generated settings and disconnecting them from their immediate physical surroundings. The concept pertains to a synthetic domain in which individuals strive for complete immersion, thus facilitating their active engagement and exposure to many occurrences (Sveistrup, 2004).

Defining the concept of MR is challenging (Rokhsaritalemi et al., 2020). Scientific studies have shown that even experts in the field need help to determine what defines MR. Speicher, Hall, & Nebeling (2019) conducted expert interviews with various academic and industry stakeholders to elucidate the main characteristics of the concept of MR. Based on the research findings, it can be stated that MR is commonly associated with the terms AR and VR. Sala (2021) defines MR as a medium that combines physical and virtual environments through immersive, computer-generated settings. This concept can be easily grasped when considering Milgram and Kishino's (1994) perspective.

As an overarching term, XR encapsulates the entire spectrum that Milgram & Kishino (1994) delineated. XR transcends the confines of AR and VR, encompassing a continuum of immersive experiences from augmented real-world environments to entirely virtual ones (Ziker et al., 2021).

XR usually acts as an inclusive umbrella term, acknowledging the interplay and convergence of virtual and real-world elements. Nonetheless, researchers have discussed the significance and relevance of the letter X in terms of XR. One perspective argues that the X is inaccurately interpreted as extended, as VR does not extend reality but substitutes it. X in the proposed interpretation can be replaced with the actuality utilised in the development, similar to an algebraic variable. It can be interpreted as future developments, which refer to the unknown reality that lies ahead (Rauschnabel et al., 2022)

Lee, Moon, Ko, Lee, & Yoo (2020) state that the concept of XR, which combines VR and AR, is becoming increasingly popular as it revolutionises how humans interact with the digital and physical realms, providing users with novel perspectives and methods of engaging with their surroundings. As a result of its radical redesign of the software user interface, XR introduced unknown challenges, which were noted in the discourse of UX experts.

The primary focus of UX for screen-based software was optimising the user interface to meet the users' needs and expectations and essential business key performance indicators (KPIs), such as conversion rates. Meanwhile, in XR environments, where all senses are fully exposed to artificial and immersive stimuli, the directness and impressive potency of the UX impose an entirely new set of obligations on designers. Exploring the user's emotions and gaining their trust is essential when designing the user interface of XR software (Hillmann, 2021).

3. Aim of the Research and Methodology

The research aims to improve an XR software program prototype for modelling agencies through empirical usability testing and analytical assessment.

The research plan was designed to answer the following research questions:

- What are the user needs for designing XR spaces?
- What are the similarities and differences between empirical and analytical user feedback?

3.1 Introduction of the Prototype of the XR Software

The software prototype is a high-fidelity product developed by a Hungarian IT company specifically for the Meta Quest 2 device. The software enables fashion companies to view models from an existing model agency, assisting decision-makers in selecting future collaboration models in an XR environment. Using a head-mounted display, fashion professionals can pre-screen and select models without travelling, saving them considerable time and effort (Figure 2).

Figure 2. The Meta Quest 2 head-mounted display and the XR fashion model selection software handles.

The main innovation of the development is that users can interact with UI elements using their hands instead of relying on a control tool to navigate in an immersive environment. This is made possible by the hand-tracking feature, which utilises software to track and map hands (Figure 3).

Users can view the models' presentations and catwalks in various environments ("Rooftop" and "Studio"). Besides that, models can be selected as favourites and then emailed to the decision-makers at the model agency.

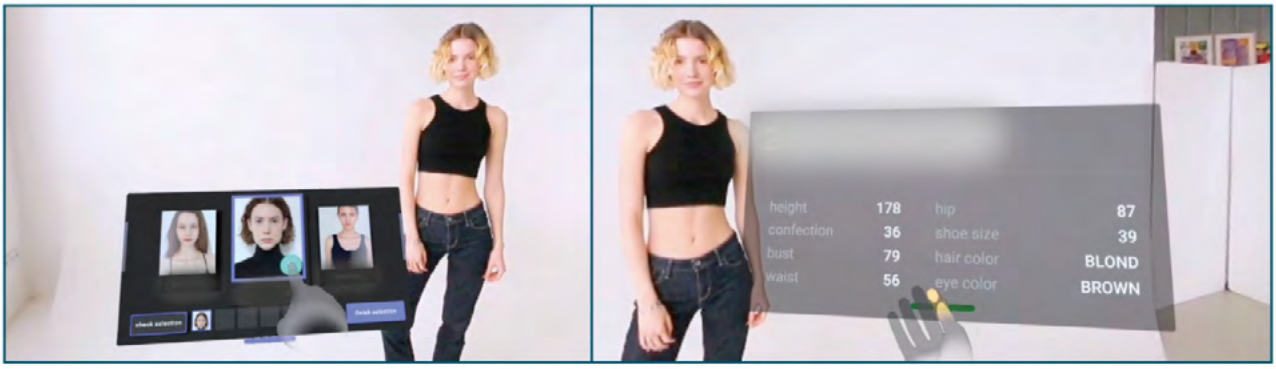

Figure 3. Hand-tracking control and parts of the XR fashion model XR software's user interface.

3.2 Research Methods

The study was consecutively divided into two qualitative sections in the spring of 2023. The first was an empirical usability study (n=13), using a pre-designed study to identify usability issues in the XR environment (Svedberg, 2020). Besides that, we supplemented the usability testing methodology with a System Usability Scale (SUS) questionnaire to assess the software quantitively by the participants (Grier et al., 2013). To gain a deeper understanding of user expectations, the experiment concluded with a follow-up interview in each case.

In the second phase, we used an analytical approach as a heuristic evaluation (n=6), in which digital product design experts offered comments on the specific software product and the XR environment (Becker & Freitas, 2023). The tests were conducted this way because, when designing an innovative product, it was vital to get feedback from potential consumers and experts to steer the prototype in the right direction.

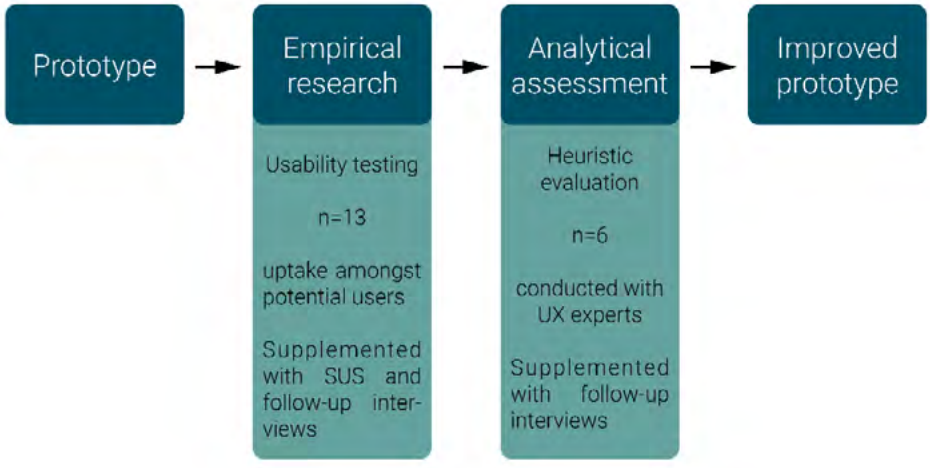

Figure 4. Research plan.

Methodological details of the empirical research:

- Usability testing

Usability testing is a qualitative approach that utilises user testing to assess various software products (Issa & Isaias, 2022). The method examines how well a product can be used for its intended purpose and evaluates whether specific product functions are met. The methodology assesses if an interface is usable by its intended users to carry out the tasks it was created for (Rubin et al., 2008).

We conducted the test using Rapid Iterative Testing and Evaluation (RITE). RITE is a usability test variation that emphasises quickly identifying and implementing solutions rather than pinpointing problems (Medlock et al., 2005; Szabó & Hercegfi, 2023). After conducting usability testing with a small group of participants, we refined the software based on user feedback for the subsequent testing phase. This ensured that modifications were made using a user-centred and iterative approach.

The usability study was carried out in three phases with varying numbers of participants: the first with four, the second with five, and the third with four individuals. Most participants were university students at the BA/BSc, MA/MSc, or PhD level, aged between 20 and 34 years (Table 1).

The development team had a two-week period to implement the modifications identified during the iterative phase before the next round of testing.

Table 1. Demographic information on empirical research participants grouped by iterative phase.

Iterative phase	1	2	3
Number of participants	4	5	4
Identification numbers	ID1, ID2, ID3, ID4	ID5, ID6, ID7, ID8, ID9	ID10, ID11, ID12, ID13
Age range	20-23	20-24	23-34
Gender distribution	Male (100%)	Male (20%), Female (80%)	Male (75%), Female (25%)
Studies	mechatronics engineer, electrical engineer, computer engineer, international management	industrial designer, psychology	computer vision, oriental languages and cultures, molecular bionics, building services engineer

During the usability test, participants were required to solve model selection tasks and scenarios outlined in predetermined descriptions. The scenarios outlined specific business challenges faced by a senior employee at a fashion agency, allowing participants to easily relate to them and creating a clear decision-making situation. To obtain a more comprehensive understanding of users' requirements, the think-aloud protocol was applied to understand the user's cognitive processes during their interaction with the product. (Jääskeläinen, 2010). Continuously using this moderation technique throughout the usability testing would likely introduce bias in the immersive environment. We created the protocol with concurrent probing (CP), a moderation technique where participants respond to questions from the facilitator at different stages of the task solution (Usability.GOV, 2013).

- System Usability Scale (SUS)

After usability testing, the research progressed by administering a System Usability Scale (SUS) questionnaire to quantitatively assess the software's usability (Bangor et al., 2008). SUS is a widely used user-centred method in scientific research and industrial practice to measure subjective usability. The questionnaire was primarily designed to assess the overall usability of complex systems and is also suitable for evaluating XR software products. The questionnaire evaluates the user's views on the system's usability using a five-point Likert scale and ten statements. The System Usability Scale (SUS) consists of an equal number of positively and negatively worded statements that are used to derive a percentage score ranging from 0 to 100 (Lewis, 2018).

- Follow-up interviews

After finishing the SUS questionnaire, participants could express their opinions about the XR software in follow-up interviews. We inquired about their cognitive processes during the tasks, enjoyment of the software, and motivation to use it. The interviews explored the participants' experiences with hand tracking as they used it to operate the software programme.

Aside from the visual aspects, the interview questions focused on immersion, precisely the arrangement of software elements in the XR environment and evaluating the auditory features (model presentations and the audiovisual effects) of XR fashion shows.

Methodological details of the analytical assessment:

- Heuristic evaluation

Heuristic evaluation is a commonly used method in industrial UX practice where a small group of experts assess the user interface's suitability for the design problem based on established ergonomic guidelines (Delice & Güngör, 2009). When evaluating screen-based software products, evaluators frequently employ established guidelines (e.g., Shneiderman, Nielsen) to assess the user interface (Delice & Güngör, 2009). Given the unique features of the XR environment, experts were asked to conduct a comprehensive and expert evaluation of the XR environment, openly addressing all relevant UX factors. In the absence of predetermined guidelines and checklists, evaluators possess the capacity to approach interface evaluation with a flexible mindset (Nielsen, 1994). This approach facilitates the identification of novel issues or opportunities that might remain overlooked when employing rigid criteria. Consequently, evaluators are empowered to leverage their creativity and domain expertise, enabling a holistic assessment of the interface encompassing aspects such as aesthetics, overall functionality, and other pertinent factors influencing UX. Heuristic evaluation thus prioritises the collection of comprehensive feedback concerning the efficacy of an interactive system, eschewing the mere enumeration of issues based on specific usability principles (Hertzum & Jacobsen, 2001). During the heuristic evaluation, we also implemented the think-aloud technique to enable participants to rapidly articulate their professional thoughts (Alshammari et al., 2015).

Six individuals with extensive experience in UX design or previous VR/AR projects participated in the study (Table 2).

Table 2. Demographic information on analytical assessment participants.

Identification number	ID1	ID2	ID3	ID4	ID5	ID6
Age	43	30	31	48	43	40
Gender	Male	Female	Female	Female	Male	Male
Experience in years regarding UX	8	1	9	7	20	24
Current work	Researcher on VR development in human resources (HR)	Junior researcher of an interaction and immersive research group	Senior researcher in the field of human-computer interaction (HCI)	Freelance web designer and developer	Mentor of designers and product design managers	UX consultant and design team mentor

- Follow-up interviews

After the heuristic evaluation, experts participated in a follow-up interview to discuss their subjective experiences and professional insights. We also sought to understand the participants' perceptions of the XR environment, its influence on them, and the emotions it elicited. We also requested their input on the professional suitability of the hand-tracking feature and any ergonomic challenges they faced. We asked the experts to provide information about themselves, including their current activities, areas of interest, research field, and experiences.

4. Results

4.1 Empirical Research Results

The results of the empirical research are presented in three iterative phases, following the characteristics of usability testing, which was applied to the RITE methodology.

- Usability testing results (iteration phase 1)

During iteration phase 1, the model selection process proceeded without any issues. When asked to select a particular model, comparable results were noted. The majority of the participants found this task easy to solve. One considered the "Add to favourites" option not the default choice for a final selection but a preliminary selection for further consideration. The text "Add to favourites" confused some of the participants as they expected a different function: "I thought it would lead to a separate list of favourites, like on clothes shop websites." (ID4)

Multiple users experienced a sudden limitation in their field of view at the periphery of their visual boundaries while using the software, leading to discomfort: “I feel confined and restricted, like being in a matchbox.” (ID1)

The initial pop-up window provided instructions on hand-tracking control, but the model selection area appeared in the background, leading to confusion among the participants during the onboarding process. During usage, participants found it beneficial to observe the outline of their hand while manipulating and moving through the XR environment using hand tracking, eliminating the need for extra information. They

claimed that onboarding not, but affordances and past physical life experiences aided their intuitive understanding of control.

The hand-tracking technology was criticised solely for its sensitivity. The participants found it frustrating when the software failed to accurately detect the users' intentions. A moderator had to help a participant activate the button he wanted to press during an assignment. The issue arose from the user's lack of perceived tactile feedback in the software, leading to uncertainty in interacting with the button: “I struggled because I had only lightly touched the button.” (ID3)

ID3 was also unsure about interacting with different elements during the usability testing due to his lack of familiarity with the hand-tracking mode of operation. Despite its challenges, the hand-tracking control was seen as a positive feature of the XR software.

Participants encountered difficulties multiple times while in the XR environment, failing to find tutorial videos or additional onboarding support during usage to overcome the problem.

The models' proximity particularly unsettled participants. Therefore, they looked for traits that would allow them to stop the models in space. During the "Introduction" mode, they struggled to understand and analyse the models' speech due to the audio recording quality.

The participants reported that the user experience was greatly improved by the highly realistic way the models moved and the presence of various locations. The rooftop view was described as "dizzying," suggesting it was authentic and made the participants feel like they were there.

Participants expressed a positive impression of the XR software during follow-up interviews, describing it as "futuristic" and "very exciting." They verified the recognised usability issues, such as onboarding difficulties and hand-tracking limitations. They expected a bright future for XR software in different sectors, including home decoration, driver's licence acquisition, long-distance travel, virtual amusement parks, and online conference participation, with possible cost reductions in a business setting. Some participants emphasised the need for increased realism in the XR environment and technological advancements to improve the user experience.

- Usability testing results (iteration phase 2)

Participants did not encounter navigational difficulties when selecting models in iteration phase 2, but some needed help establishing the selection criteria. Participants remarked that the XR environment was blurry, especially towards the edges. As a result, many participants needed help understanding the characteristics of the models.

Some criticised the software's user interface for having elements that were too closely positioned and being interrupted by disruptive pop-up windows.

Participants rapidly left the "Rooftop" view due to distractions caused by the white background behind the models, prompting several users to quickly switch to the "Studio" view because of feelings of spatial anxiety.

Participants in Iteration 2 were concerned about models approaching too closely in catwalk mode, prompting them to seek software solutions to prevent this.

The low audio recording quality made understanding and analysing the models' introduction challenging: “I was annoyed by the models' constant speech, so I tried to keep it under control.” (ID6)

Participants' perceptions of being within the XR environment space varied. Some participants were dissatisfied as they could not experience detachment from reality: "I could see through the bottom of the glasses, so it was less realistic.” (ID5)

In addition, some participants in the usability testing expressed concern about being in a physical environment: "I was afraid of hitting the real wall.” (ID7)

The hand-tracking feature generated mixed reactions from the participants. All of them were irritated since the software often failed to react to button pushes, and it was unclear how to click. Nonetheless, they enjoyed it due to the novel and unusual experience: "It was interesting to press into the space and interact with something." (ID9)

Several participants, however, claimed that calculating the proper distances to reach the buttons took much work. Some said that activating the buttons with one finger was complicated and annoying (both found it easier to contact the button with two fingers). Some participants recommended creating an onboarding solution that includes all manipulation operations to overcome navigation issues.

Participants maintained a positive impression of the XR software during the interviews in iteration 2, describing it as "great," "exciting," and "particularly interesting." Interviewees appreciated the realistic environment and the opportunities for controller-free interactions. Feedback was generally positive, although some struggled with pop-up windows. The importance of onboarding was highlighted. Participants predicted increased adoption of XR software for design, medical applications, office work, entertainment, and business meetings but emphasised the need for improved immersion.

- Usability testing results (iteration phase 3)

In iteration 3, the model selection process was relatively easy. However, there were visual disturbances in the XR environment, with the space shaking and blinking at the start. Several individuals have raised concerns regarding the image quality of the stationary models.

The revised panel layout implementation after iteration phase 2 was successful, leading to enhanced clarity and transparency in the user interface.

Pressing buttons continued to present difficulties due to the need for tactile feedback. Furthermore, the system's slow performance impeded the software's navigation.

The participants found the software's response time slow and were unsure why they couldn't press a button or activate a function. Participants also complained about the lack of clarity in the system's feedback: “The response of the overall environment is painfully sluggish.” (ID11)

Frequently, the pop-up panels were positioned too close to the user, causing the text to be difficult to read. Most people instinctively reacted by stepping back: "I want to move away”. (ID10)

The "Rooftop" perspective caused users to lose their sense of space, leading them to prefer the "Studio" view: “The studio perspective was more realistic.” (ID13)

Hand-tracking generated negative feedback during this iterative phase, most likely as a result of the slower system speed of the improved prototype: "The hand control is unusual and odd. I don’t like it." (ID12)

Participants in the interviews expressed positive assessments of the design of the XR space, particularly appreciating its cleanliness and intuitive structure. They recommended improvements like increasing the size of action buttons and text and adding arrows for straightforward navigation. The need for more onboarding information and irritating pop-up windows were also mentioned. Some users expressed dissatisfaction with the display quality and the lack of background music. Participants acknowledged the software's potential for academic and recreational purposes, foreseeing a promising future but recognising the necessity for additional improvements.

- System Usability Scale (SUS) results

The SUS questionnaires validate the findings of the usability studies. During iterative phase 1, participants assessed the software product's usability with a mean score of 77.5% and a standard deviation (SD) of 6.12. In iterative phase 2, the mean was 76% (SD=11.81); in iterative phase 3, it was 78.75% (SD=4.33).

The high SUS values were attributed to the participant's ability to appreciate the novelty of the software. The XR Environment and the innovative hand-tracking control overcame several minor issues identified for improvement in the usability evaluation.

4.2 Analytical Assessment Results

The results of the analytic examination are provided alongside the follow-up interviews, in which the experts primarily re-emphasized, clarified, and concluded the issues raised throughout the inquiry.

- Heuristic evaluation results

The experts' overall product assessment was optimistic based on the heuristic tests.

All experts felt confused throughout the onboarding process since photos were utilised to demonstrate non-interactive capabilities. As a result, most of them raced through this portion without thoroughly reading the directions.

During model selection, there were several instances where participants mistakenly pushed the selection (+/-) button while scrolling (swiping) between models, deleting or adding models to the selection.

The models' proximity distracted everyone in the area, leading users to step back: "I have to step back to see the legs." (ID2)

The aesthetics of the panels provoked various emotions among the participants. They were all pleased with how the content was organised, but using colour, contrast, proportions, and alignment within the panels was controversial.

Moving the panels was a common challenge. Some couldn't recall how to move them, while others decided not to make the appropriate motion. Many people saw the panels as static, preferring to adapt their stance to their surroundings.

At the end of the selection process, everyone was frustrated and unclear about the "done" feedback, which appeared interactive but produced no change or input. Moreover, it was necessary to clarify what actions to take and whether the selection had been accurately submitted.

Hand tracking received a wide range of reviews, with some considering it immature and complicated, while others found it simple and enjoyable to use.

> "What I found more challenging than my prior controller experience was the absence of tactile input when I hit the button. It made it much more difficult to understand how hard to press was. It's also unusual to see a panel and occasionally have to press behind it." (ID2)

In other situations, the issue was that they found it challenging when they attempted to break from the tool's usage patterns (2D tools). Manual navigation includes all interactions inside the software; even specialists reported a high sense of uneasiness among users about whether they were doing something wrong. When a gesture did not work the first time, many people would try a more extensive interface, palm or multiple fingers, and maybe double- or many consecutive clicks to remedy the problem.

> "I was trying to pick up patterns of behaviour that we use on 90% of devices, so it was a bit weird for me to find out ... that I was touching it and moving it, but it was cool."(ID4)

Overall, participants indicated good feelings about the XR program and constructive remarks concerning the space's architecture and increased realism.

> "The direction is nice from a UX standpoint. I believe it tries too hard to mimic real-life, realistic model choices while failing to realise the space's possibilities completely. It's a good thing there aren't any hidden panels because I believe they detract from the added real-world potential that comes from the fact that the area is completely changeable. I suppose people are seated in a typical model selection, but I can also envision them moving about, etc." (ID6)

5. Discussion

The applied research methods proved effective, and the empirical and analytical studies have revealed a relevant set of user needs that can support the user-centred development of the XR prototype.

The onboarding part of the software is likely to receive greater attention and engagement if it were interactive. To inform users what actions they can take in the XR environment, additional information should be added to the software features during the onboarding process (e.g., introduction of models, catwalk function, steps of the selection process).

After learning how to move the panels, everyone was eager to customise the interface. In addition, individual panel layouts should be saved, and it would be helpful to demonstrate this to users during onboarding.

After customising the user interface, the specified location of the pop-up windows caused issues in all testing to varied degrees. This was due to information showing behind other windows outside the perimeter. Because some of these elements were fixed, the users had to adjust their location relative to the panel to proceed.

As the users perceived the introduction to allude to a spoken speech, this feature proved to be deceptive. Therefore, it would make sense to incorporate a more direct and personal introduction to the models into the software. While it is true that the selection process is impersonal in real-time, the models might be placed in the XR environment closer to the decision-makers, for example, by providing optionally displayable extra information about their residence, hobbies, and modelling experience, among other things.

Users also felt they could not control the software because of the instantaneous, self-running video of the models. The models' inconsistent stopping points at the end of walks, which caused the movements to terminate in the middle of the sequence and gave the appearance of a software freeze, proved confounding in a few instances.

The demand for personal space is also evident in the XR environment because the models come uncomfortably close to the users. The design should ensure that the users do not feel that any part of the user interface is disturbing their personal space.

Users found the hand-tracking feature innovative and intriguing, yet they believed it required improvement.

Making the software more user-friendly would include translating components from ordinary life and reality into immersive environments. These solutions may include lifting the panel with two hands, like lifting a sheet of paper, or even a virtual board, like a corkboard, on which you could use tweezers to place pictures of particular models. (Figure 5).

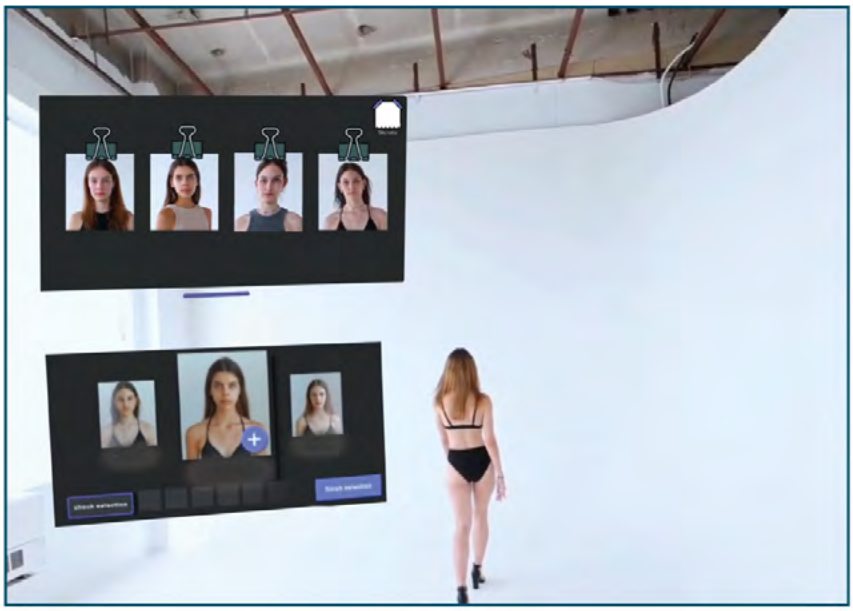

Figure 5. An example of using real-life boards and tweezers to increase the realism of the workflow in the XR environment.

The "done" caption at the end of the selection process was troublesome and caused doubt and annoyance, significantly reducing the UX. The system did not indicate that clicking on it would prompt the user to take action.

These insights will significantly help customise the software and XR environment to meet the user's needs. In the future, educating potential users through well-designed onboarding will be essential for users of XR software to be informed about, utilise, and benefit from the opportunities provided by the immersive environment.

6. Conclusion

In terms of the applied methodologies, participants in the empirical research found a notably more significant number of design flaws (such as distracting background colour and smaller button sizes) that were easily fixed but had no impact on UX. Of course, similar observations were also made during the analytical assessment. Still, the experts were concerned about more profound factors that could impact UX, such as overcrowding, consistency problems, and recurring errors in design (e.g. inadequate location of pop-up windows, lack of feedback).

The empirical research highlighted the lack of guidance and training on correct gestures, particularly about software usage. Furthermore, the analytical study discovered other significant results. These insights involved integrating components that were already present in various applications and real-world scenarios. The analysis confirms that XR software design should follow traditional UX design standards (e.g. Shneiderman's guidelines). The heuristic assessment found instances where it was suggested that the XR environment should allow the user to take control of the conversation, such as following traditional design principles. Users should be able to start and stop the video manually, and a progress indicator should display their position on the timeline.

The models selected in several cases were chosen randomly, and the analytical assessment offered a sophisticated improvement proposal to address this. The experts emphasised that errors could be reduced by placing the action button that triggers the selection in a separate bar from where users intended to scroll. Moreover, using the familiar check box instead of the selection option can help streamline the process. The participants in the empirical study made many general suggestions about expanding or limiting the selection options but did not offer any specific advice.

Aside from optimising load times and durations in different use cases, focusing more on specific aspects like hand gestures, visual prompts, movement, and sound design in XR environments is crucial.

Experts assert that allowing the user to have control over the design of their XR environment and the ability to add panels to customise it is crucial.

Creating software versions for different age groups is necessary due to the product's compatibility with diverse users and their significant usage habits. One way to achieve this is by incorporating various features to help users unfamiliar with technology, such as providing thorough onboarding, implementing hand tracking, and including traditional features like a drop-down menu. These characteristics should be optional or deactivated once abilities and routines are established.

Moreover, the analytical assessment also showed an improvement in ecological validity. Examples include integrating functionalities from different software, such as note-taking, video scrolling, and profile settings, and implementing real-life gesture recognition, like lifting a panel with two hands like a sheet of paper. Contact with other individuals in the XR area and realistic mapping of real-life movements, like sitting on a couch, changing perspectives, and exploring models, have been proposed as essential.

It can be said that both empirical and analytical studies have provided useful feedback. The fundamental difference is that the analytical insights were more comprehensive and thus can be used to design any XR circular design so that their consideration highly enhances the UX of the software. In contrast, the empirical results gave concrete development ideas for concrete software. The joint observation involved enhancing non-design parts (such as controls and audio-based sub-elements) to enhance the overall realism of the environment (Table 3).

Table 3. Summarising the results of empirical and analytical usability studies

Empirical research	Analytical assessment
Design flaws (e.g. distracting background colour, smaller button sizes)	Overall design insights (e.g. overcrowding, consistency, recurring design errors)
Inappropriate visualisation, location and grouping of functions	Ability to customise panels and settings, furthermore creating software versions
Absence of onboarding	Developing product learnability (beyond onboarding)
Greater emphasis on certain aspects of the whole environment (e.g. hand gestures, visual prompts, movement, sound design)	

6.1 Limitations

Consequently, when creating an XR software product, an analytical assessment is recommended after developing a high-fidelity prototype in the initial iteration. After considering the suggestions of analytical assessment and constructing the product, empirical usability testing is a valuable tool.
The empirical research should have a 2-week development duration to implement the development ideas effectively. One limitation of our study was that the participants fell within the age range of 20 to 34. Thus, we could not collect the viewpoints and experiences of other potential users.

We could not hire fashion industry experts because of the significant financial implications. Upon product completion, it would also be advantageous to gather their feedback.

The experts who participated in the analytical assessment included some with less experience in UX (e.g. ID2) or no experience in VR/AR development (e.g. ID4). This may have slightly affected the results.

About the Authors:

Bálint Szabó, assistant professor at Budapest University of Technology and Economics, delves into user-centered software development in his doctoral dissertation. Specializing in Human-Computer Interaction (HCI) research, he focuses on eye-tracking methodologies.

Rita Ladjánszky, an industrial design engineering student at Budapest University of Technology and Economics. Researching XR products and software usability testing methodologies, she earned top honors at the 2023 Scientific Student Conference and a Pro Progressio fellowship for her work.

Pataki-Bittó Fruzsina, assistant professor at Budapest University of Technology and Economics, focuses on employee-centered development of office work environments. She leads the Future of Work community within EELISA, collaborating with Hungarian and international students on future workplace projects.

Sarolta Tóvölgyi, assistant professor and Erasmus coordinator at Budapest University of Technology. Her doctoral focus is on ergonomics-driven product management for blood group serology equipment. She excels in user-centric product development across various physical products.

Kata Kapusy, assistant professor at Budapest University of Technology and Economics, explored consumer purchasing behavior in second-hand clothing shopping for her doctoral dissertation. With a focus on human factors, she delves into in-store and user-centered XR software research.

Acknowledgements: We would like to thank the students involved in the product-user interaction for their assistance in carrying out the empirical investigation. We would also like to express our gratitude to the UX Budapest group members for their enthusiastic participation in the analytical investigation.

ABSTRACT | The emergence of concepts such as pervasive computing, blended spaces, augmented and virtual realities, related here to technologies associated with so-called extended reality (XR), challenge many of the best practices associated with user-experience design (UX). In particular, the environmental qualities of XR technologies that require a strong synthesis of digital content with, and within, virtual and physical socio-spatial contexts challenge many aspects of product-oriented approaches to digital design. As interaction design (IXD) lecturers who have spent much of the last two decades focused on developing approaches and methods for teaching the design of digital products such as websites and mobile phone applications, we recognize that preparing students for future careers involving the design of XR systems requires reconsideration of theories and practicalities that have become entrenched over the recent past in digital design education and practice. Furthermore, as educators working in the Global South, we aim to engage with the constraints afforded by limited access to much of this high-end technology in a designerly manner. In response, this study addresses two objectives: firstly, to engage design students with technologies in a more systemic manner, focusing on interrelationships of socio-spatial temporal contexts and XR technologies, recognizing student's prior knowledge of UX while not being beholden to it; and secondly, to ensure a criticality in the resulting process towards design outcomes which extend beyond subjective speculation to incorporate evaluative reflection.

1. Introduction

As interaction design (IXD) lecturers who have spent much of the last two decades focused on developing approaches and methods for teaching the design of digital products such as websites and mobile phone applications within a user-experience paradigm, we recognize that preparing students for future careers involving the design of extended reality (XR) systems requires reconsideration of theories and practicalities that have become entrenched over the recent past in digital design education and practice. Here, we understand XR as a composite term for a collection of diverse digital fields unified by a focus on spatial computer interactions (Hillmann, 2021, p. 241). These include virtual reality (VR), augmented reality (AR), blended space design (BSD), as well as smart things and environment design.

Furthermore, within what we associate with the normative conventions of user-experience and service design practices, we have also begun to experience a lack of technique for adequately communicating and evaluating, high-level strategic thinking at the level of systems, services, and environments. This limitation, brought about, we would argue, by a product orientated legacy is a general concern for human-centred design practices highlighted by their struggle to address complex, large-scale systemic problems (Mani-Kandt, 2021). However, for XR design, due to its implicit focus on environmentally structured solutions, the need to ideate at a level detailing the value of systemic solution formation is a fundamental.

With these concerns and concepts as an initial point of departure, this study describes what we would refer to as the opportunistic design of a new teaching unit, positioned at the third year of a three-year digital media design program, taught in the Department of Multimedia at the University of Johannesburg. We refer to our approach as 'opportunistic' because while our essential responsibility was to deliver a unit that introduced students to XR broadly, and to IXD concepts and techniques relevant to XR, our recent teaching practices have begun to appreciate futures thinking. That is, design fictions (DFs) is broadly considered as a conceptual approach for projecting proposed complex design scenarios in accessible relatable, and evaluable forms. Furthermore, drawing on previous experiences teaching Internet of Things-themed projects, we have recognized the positive impact of visual storyboarding for the communication of complex, innovative solution systems. Lastly, while recognizing key differences between spatial and product-oriented design, we wanted to leverage student's prior knowledge of UX/service design research, analysis and strategic thinking and communication.

Consequently, and drawing on tacit and explicit objectives for the teaching unit, this study addresses two objectives: first, to engage design students with technologies in a more systemic manner, focusing on interrelationships of socio-spatial temporal contexts and XR technologies, recognizing student's prior knowledge of UX while not being beholden to it; and second, to ensure a criticality in the resulting process towards design outcomes which extend beyond subjective speculation to incorporate evaluative reflection. In this regard, the study articulates the key considerations that informed the design of the teaching unit, the application of the unit in the context of our experience teaching it, and a selection of reflections outlining a set of general insights and perspectives gained from these activities.

2. The Design Landscape of the XR Teaching Unit

This study, and its summative contributions, are contextualised within a taught unit of a third-year digital media design programme. As there are multiple conceptualisations of what digital media education can and should include, we will briefly provide an overview of the key design approaches and techniques that foreground the unit, and subsequently this study, from the perspective of how they are regarded in our programme.

First, our digital media programme emphasises a creative, socially aware approach to the design of digital services and systems. All students share a general digital media education that includes units dedicated to visual design, design thinking, critical design theory and professional practice but specialize in either

interaction design or digital arts. In this broad framing of the programme, the two module specialisations focus respectively on user experience design (UX) and filmic communication including but not limited to animation, motion graphics, video editing and video compositing. In respect to these two established specialisations, XR is recognized as an emerging set of design approaches and technologies that converge aspects of both interaction design and digital arts, and, it is anticipated, will become an ever more important focus in the education of future digital media professionals. Our UX approach, which all IXD students would have completed earlier in the year, is positioned as the design of interactive products and services that provide good experiences for their intended users. In the UX specialization, the notion of experience is informed by a range of critical, phenomenological and pragmatic theoretical perspectives but can generally be equated with systems and services that are enjoyable to use, are fit for purpose and enhance the everyday activities of the people who use them (Benyon, 2019). As exemplified in Table 1, the UX offering in the programme is structured on a generic design thinking process within a human-centred paradigm (Giacomin, 2014).

Table 1. Overview of UX module.

RESEARCH	STRATEGY	IDEATION	PROTOTYPING	EVALUATION	KEY CONCEPTS AND THEORY

Business by design Experience Human-centred Design

Second, and within the larger UX module design process, customer journey maps (CJs) (Følstad & Kvale, 2018) are defined as visual, typically schematic, representations of an archetypal journey, and the service environment in which the journey takes place, that an aggregate of users (customers) of a service would undertake as they move from their initial point of entry to the successful completion of their engagement with the service (Adaptive Path, 2013). Typically, CJs reflect the users' journey, across multiple interactions, touchpoints and channels. In this manner, CJs can be considered as a type of service blueprint (Polaine, Løvlie, & Reason, 2013, p. 91) that emphasize the 'front-end' relationship between customers and a specific service.

As noted in Table 1, CJs are applied in two differing ways in our taught UX process. The first application is to map current services or environmental contexts, typically highlighting 'pain-points' and other opportunities for design intervention. The second application is the use of CJs to project an envisioned service or systemic solution. In this application, CJs provide the service context for the subsequent development of potentially multiple, composite digital, non-digital and blended products and environments. A critical point that we identify in CJs used in this manner, is that they are the key conceptual pivot in the design thinking process that both account for the data-driven, but inherently subjective framing of the design problem, and the responding proposed strategic and tactical approach for resolving the design problem.1 It is this second interpretation of CJs that is the ongoing focus of this study. Third, as described in Section 5, students were tasked with engaging with the specific XR practice of blended space design (BSD). BSD can be understood as a spatial view of IXD and UX (Benyon, 2014, p. 1) concerned with the integration of physical and digital spaces to create novel ways for people to engage with the world around them (Benyon, 2014, p. 80).

[1] This consideration draws on Cross and Dorst's notion of problem-solution conjectures in the resolution of wicked problems (Designerly Ways of Knowing, 2006, p. 80).

Lastly, in the context of this study, 'design fictions' refer to designed artefacts that embody and communicate concepts as opposed to offering any utilitarian function. While the concepts of DFs has its precedent in the discursive design fields of speculative design (Dunne & Raby, 2013), (Tharp & Tharp, 2018) and design fiction (Bleeker, 2009),2 in this study, DFs are framed in reference to an emerging set of design research approaches including metrofitting, (Fry 2017), projective research (Geldof & Janssens, 2014; Figueiredo, 2020), and anticipatory design research (Morrison, 2018) that employ DFs to enquire into "putative and contingent" states to "reach for tomorrow's worlds today" (Morrison, 2018, p. 125). The central tenet of these futural approaches is not to predict a definitive future but rather to anticipate possible, plausible futures ultimately relating to concepts of "preparation, expectation, and valuing something probable" (De Smet & Janssens, 2016, p. 2762). Towards this agenda, these anticipatory practices employ DFs to suspend belief about functional and immediate contexts and to challenge audiences to think beyond their expectations and comfort zones (Morrison, 2018, pp. 123, 129), and, as such, expose and explore the implications of plausible near futures (Lindley et al., 2015, p. 58). Examples of DFs in these approaches include highly 'scientific' mappings of future environments (Geldof & Janssens, 2014, p. 8), web-page blogs for a genetically engineered cyborg narwhale (Morrison 2018, p. 134), and streetscape leporellos describing a community's ideal future smart neighbourhood (Fenn, 2023). However, the work that resonates most strongly with our intentions for our students is O'Keefe et al.'s (2020; 2021) 'design fiction storyboards'. In these works, the aforementioned authors utilize graphic storyboards in rich visual narrative sequences to articulate a 'speculative blended experience'. Key to the effectiveness of these near future narratives is the situatedness of proposed blended technologies within very relatable, social worlds, be they the experience of a tourist attending a garden show and being gifted a digital seed to 'grow' on their computer back home, or an audience providing real-time feedback of a standup comedian performances via their smartwatches 'laugh-o-meter'.

3. Methodology

The method of the study is premised on constructive design research (CDR) (Zimmerman et al. 2007; Forlizzi et al. 2008; Zimmerman & Forlizzi 2014; Forlizzi et al. 2014), a general methodology for practising research through design or in our case, research through design teaching. The research contribution of CDR is concerned with holistic practice, that is, how researchers have framed and responded to complex problems and how they have negotiated the various paradoxes, conflicts, and intersecting perspectives to create the 'right thing' (Zimmerman et al. 2007, p. 498; Zimmerman & Forlizzi 2014, p. 177). In the case of this study, the 'right thing' was conceived as the teaching unit described in 5. The Design Process. Following, Zimmerman and Forlizzi (2014, p. 185) we first provide a high-level description of the range of activities involved in the design process of the teaching intervention. This process description is followed by an evaluative discussion reflecting on the *Process, Relevance, Invention* and *Extensibility* (Zimmerman et al. 2007, p. 499; Forlizzi et al. 2008, p. 27) of the designed teaching intervention.

4. Limitations of this Study

This study is primarily concerned with the methodological development of the teaching unit within the design contexts of XR, UXD and anticipatory DFs. As such, its focus is largely on our experience as researchers and educators aiming to contribute, through our teaching practice, theoretical knowledge on a novel design technique. As such, while this research involved design students in a classroom setting it does not focus on their experience, outside of reporting very generally on their response to the project.

[2] Although, they have earlier precedents in commercial conceptual designs, such as, for example, car shows, and avant-garde design movements such as Archigram and Memphis Design.

5. The Design Process of the Teaching Unit

In the second semester of the 2023 academic year, 46 third year IXD and digital arts students from the Department of Multimedia, participated in a 12-week module, the aim of which was to critically engage learners with XR technologies from a designerly perspective.

Two objectives were formulated which would provide the foundational structure of the course. Firstly, to expose and explore Design concerns to be found at the intersection of IXD and XR through the theory. This took the form of a series of lectures which provided a theoretical and philosophical backdrop to the socio-technological contexts of XR and a discussion of related IXD principles, methods, and models. The second objective was to facilitate a practice-based learner engagement using research-oriented design practices, with a futures focus, from a systemic / services perspective, rather than a product-oriented mindset.

As the focus of this research study, the remainder of this section provides an exposition and reflection upon this second objective including the research orientation and approach, process, and outcomes of the six-week student practical project.

5.1 Practice-Based Learner Engagement

In a developing economy context such as ours, access to both XR hardware and software, and the knowledge and skills resources required to facilitate authoring with XR technology, is limited. A challenge is thus presented in having students directly engage with XR technologies in the making of design solutions for the purposes of learning.

Historically in our department, when IXD has been taught through practical assignments at the third-year level, it has been with a product-oriented mindset where students will develop (product) design solutions within the general rubric of user experience design (UX). More recently, we have worked to integrate systemic and services-oriented thinking in the development of UX strategies which first require integrated multi-channel considerations using CJs, prior to detailing user journeys aligned to digital channels and digital product design. Additionally, storyboarding CJs has been featured in our teaching smart things projects.

The intent for the practice-based learner engagement with XR technologies was thus to further develop upon the use of CJ thinking with an emphasis on (probable) projective futures rather than merely mapping. Central to the development of this intent would be exposing students to David Benyon's taxonomy of spaces[3] and his work relating to the design of blended spaces in *Spaces of Interaction, Places for Experience* (Benyon, 2014) in the IXD and XR theory classes which would precede the student's practical assignment.

Building upon Benyon's blended experiences framework (ibid), the application of design fiction storyboards towards conceptualising speculative blended experiences by O'Keefe et al (2020; 2021); would serve to complete an initial framing of our intent for a practice-based learner engagement with XR technologies.

5.2 Approach

The research orientation was developed to underpin the practice-based engagement by students integrated research as making and research in making.

As making, design fiction served as the overarching design methodology for the student practical assignment with the requirement of designing an anticipatory concept for an 'extended blended experience'.

[3] Benyon's categorization identifies physical, digital, information, conceptual and social space.

This was alternatively expressed in the student assignment brief, as an ‘extended reality experience’ (XRE) that was to be ‘anticipatory in its speculative thinking’.

The medium to be employed for the visualisation of the XRE concept was further required to take the form of a ‘comic’.[4] The student assignment brief identified the summative deliverable as a ‘graphic design fiction’ and as such, a concept was to be considered as an object of design.[5] Here, the effort of research as making aimed to tell us something about how the future could or should be designed in general relation to an engagement with XR technology. In making, the XRE concept would function as a design product which would be iterated in various forms and at various times over the duration of the practical project, culminating in a user-centered evaluation of the concept expressed as a comic. This evaluative research in making aimed to tell students something about how their concepts could or should be designed for an engagement with particular XR technologies at play in their concepts.

5.3 Process

Students were required to conceptualise and communicated an XRE that enhances the experience of Halloween for tweens (9-13 years).6 Design criteria for the XRE included: the use of both physical and digital components; presentation of an African interpretation/styling of Halloween; inclusion of services, performances, locations, objects, software, broadcast media, etc. if necessary, and; highlighting the human experience as well as key technological attributes.

The XRE concept was to be developed by students, working in pairs, over six weeks progressing through a four-stage process identified as: 1. Ideate; 2. Extend; 3. Communicate; and 4. Evaluate.

The core of the process involved developing storyboards and comic visualizations, supported by the creation of CJs in a staged progression. In this way, the XRE concept was able to be iteratively developed while each of these activities/tools influenced each other’s development. Table 2. provides an overview of this process including the time allocated to each design stage, a stage summary, activities, deliverables, and iterations upon the deliverables.

[4] Although ‘comic’ has in contemporary times been replaced with terms such as graphic novel etc., we use it here to contrast the visual literacies of comic art with the stylistic convention of storyboards.

[5] The XRE concept was required to be submitted for grading as an A3-sized printed comic.

[6] It is worth noting that Halloween is not a traditional South African holiday and has no established cultural practices.

Table 2. Overview of the Student Assignment Process.

	STAGE SUMMARY	ACTIVITIES	DELIVERABLES & ITERATIONS
IDEATE Week 1	Developing initial extended blended experience concepts (the XRE) using storyboard sketches	1. Storyboarding concepts at the detail level of stick figures and text boxes 2. Presentation of concepts for feedback	Storyboard (iteration 1) Storyboard (iteration 2)
EXTEND Weeks 2-3	Elaboration of narrative concepts in the analytic form of a customer journey	1. First draft customer journeys defining key interactions and channels for the XRE 2. Second draft journey enrichment *using Benyon's blended experience framework (2014) 3. Presentation of journeys for feedback 4. Final customer journey map deliverable	Customer journey map (iteration 1) Customer journey map (iteration 2) Customer journey map (iteration 3)
COMMUNICATE Weeks 4-5	Re-conceptualizing the customer journey as a graphical design fiction (comic)	1. Final hand illustrated storyboard for delivery 2. Creation of a first draft (70% complete) Comic for XRE concepts. ** 3. Presentation of XRE Comic for feedback	Storyboard (iteration 3) XRE Comic (iteration 1) XRE Comic (iteration 2)
EVALUATE Weeks 5-7	Audience evaluation of the graphical design fiction	1. Co-creation of evaluation tool with students 3. Evaluative-testing of XRE Comic 4. Submission of amended and final XRE Comic	XRE comic (iteration 3)

* Enrichment included consideration of ontology, topology, volatility and agency, and how they effect, and are affected by, channel correspondences as described in Benyon's Blended Experiences Framework (2014)

** At this stage, students were introduced to comics as a medium of communication

Concluding the student assignment project process, and this discussion of process, a user-centered evaluation of the XRE concepts was conducted using students to peer-evaluate the XRE comics. Prior to conducting the evaluation, a workshop was conducted, facilitated by the authors, where the evaluation of concepts, rather than a product by intended end-users, was discussed and problematized. Thereafter, students were engaged in an open session of brainstorming possible criteria for such an evaluation. Following the workshop, five criteria were taken forward for use in the peer-evaluation, where each XRE comic received feedback from five participants.

This evaluative research in making an effort constituted the last round of feedback and input into the iterative process of the development of the student's XRE concepts.

5.4 Outcomes

In total, 19 student teams received the initial assignment brief, and all went on to complete the design project.[7] All the student teams participated in the evaluative research and, with the exception of two student teams, all assignments were delivered on deadline. Table 3 presents the assessment criteria provided in the assignment brief and that was used in the grading of the projects.

Table 3. Assessment Criteria for Grading Student Assignments.

Quality of final design fiction narrative:	30%
Quality of final design fiction visualisation:	30%
Ability of customer-journey to communicate design concept visualisation:	30%
Timeously completed rough storyboard:	10%

Although a high degree of variation in quality was observable across the student teams, and across individual deliverables from across teams, all teams were able to develop and deliver XRE storyboards, CJs and XRE comics.

Three examples of student work from the design project are presented below: a storyboard (Figure 1), a customer journey map (Figure 2) and an XRE comic (Figure 3).

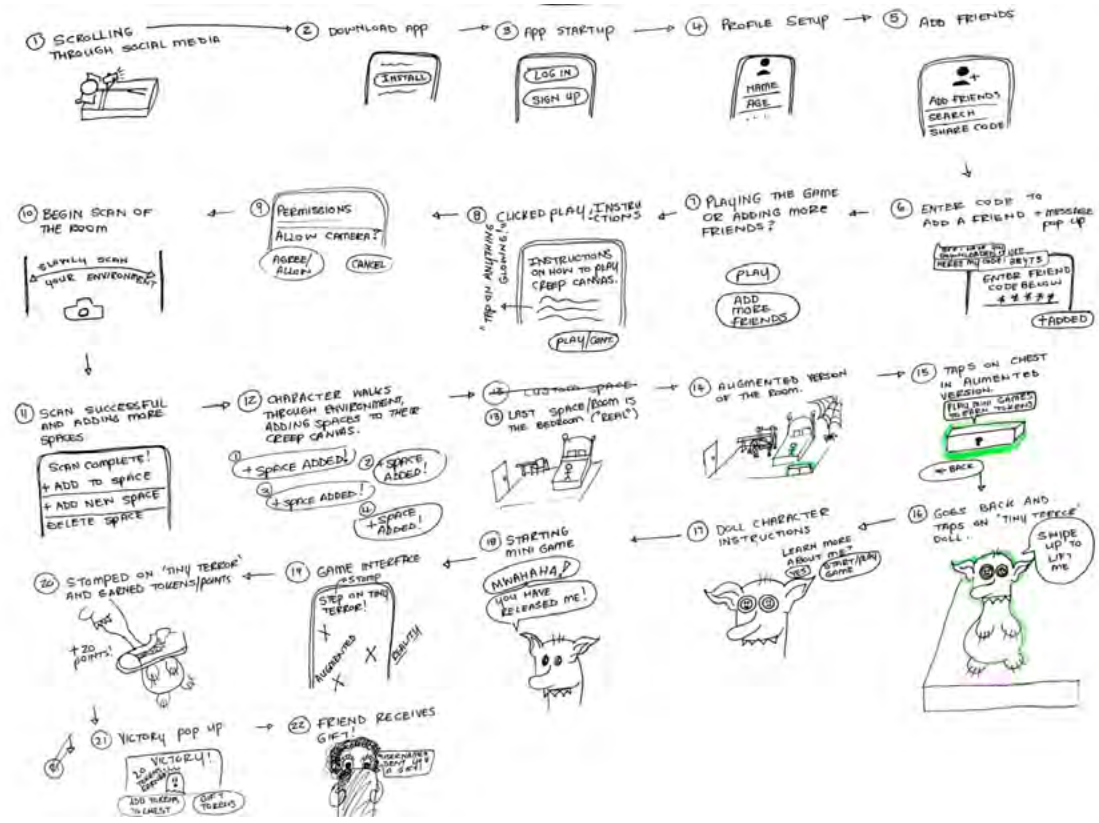

Figure 1. Example of a student group's storyboard. (Image: Sarah Davis & Devorah Hodes, 2023).

[7] The shift in language from 'student pairs' to 'student teams' relates to a small number of working groups being constituted by three rather than two students.

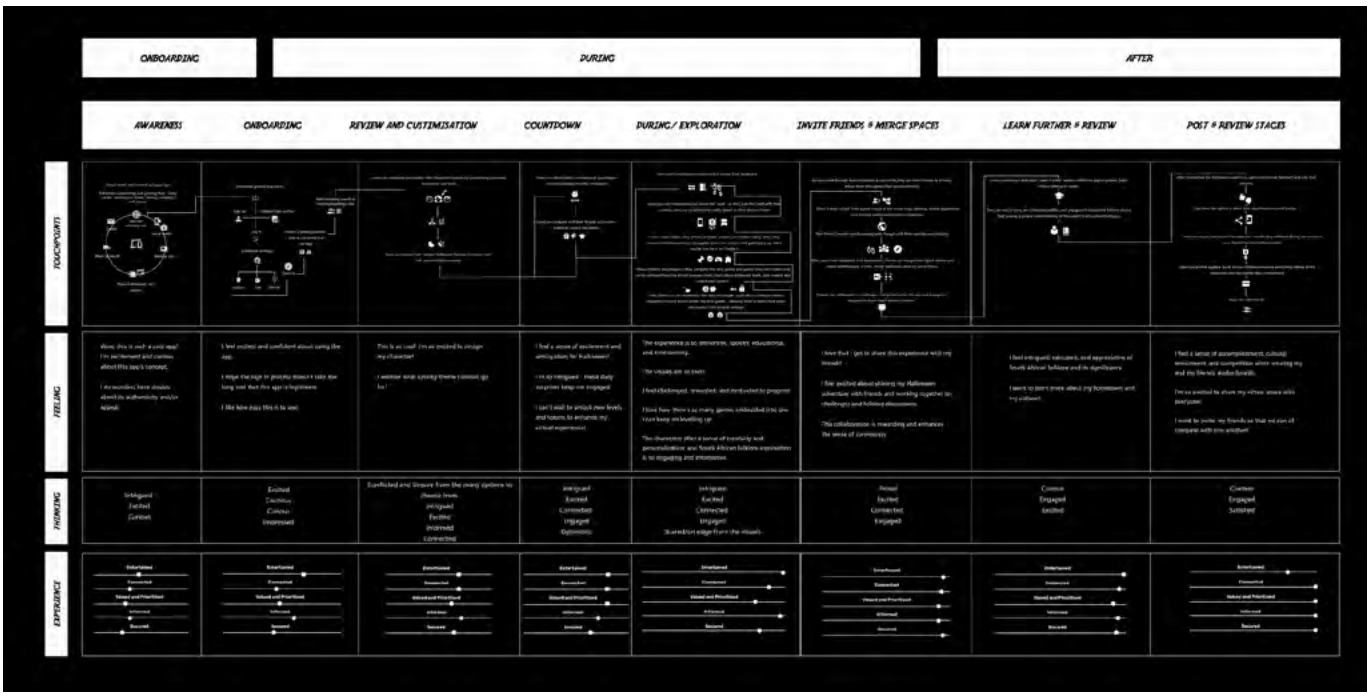

Figure 2. Example of a student group's customer journey. (Image: Sarah Davis & Devorah Hodes, 2023).

5.5 Reflection on the Teaching

Overall, we felt the project exceed our initial goals for the projected research effort and the various conceptual and theoretical threads converged in a rigorous yet enjoyable class to teach, and from all accounts to participate in as a student. At the end of the unit, students completed assignment feedback forms. The scope of feedback spanned both project objectives, the initial theoretical exploration of the subject matter and the practice-based learner engagement. Students were anticipated to have struggled more with the theoretical aspects of the unit however feedback was favourable overall.

Students are taught a number of units which focus on storyboarding and general visual design in the first and second years of their studies, however, comics as a communication literacy and visual storytelling format, do not currently feature within the curriculum of the digital media design undergraduate programme. To the student's credit, almost all teams were able to translate their storyboards and CJs into a competent comic format, but for future editions, teaching the formal elements of comic design should be factored into the structure of the unit in a considered way.

Lastly, the manner in which the user-centred evaluation played out in the design project was arguably light touch. While the workshop conducted was felt to be of significant value and peer-evaluation not without its benefits, 8 the evaluation was felt to lack the full force of feedback which can be experienced when garnered from detached participants.

[8] A notable benefit of peer-evaluation considered by the authors, is how participants might come to reflect more critically upon their own concepts and designs through the act of evaluating those of their peers.

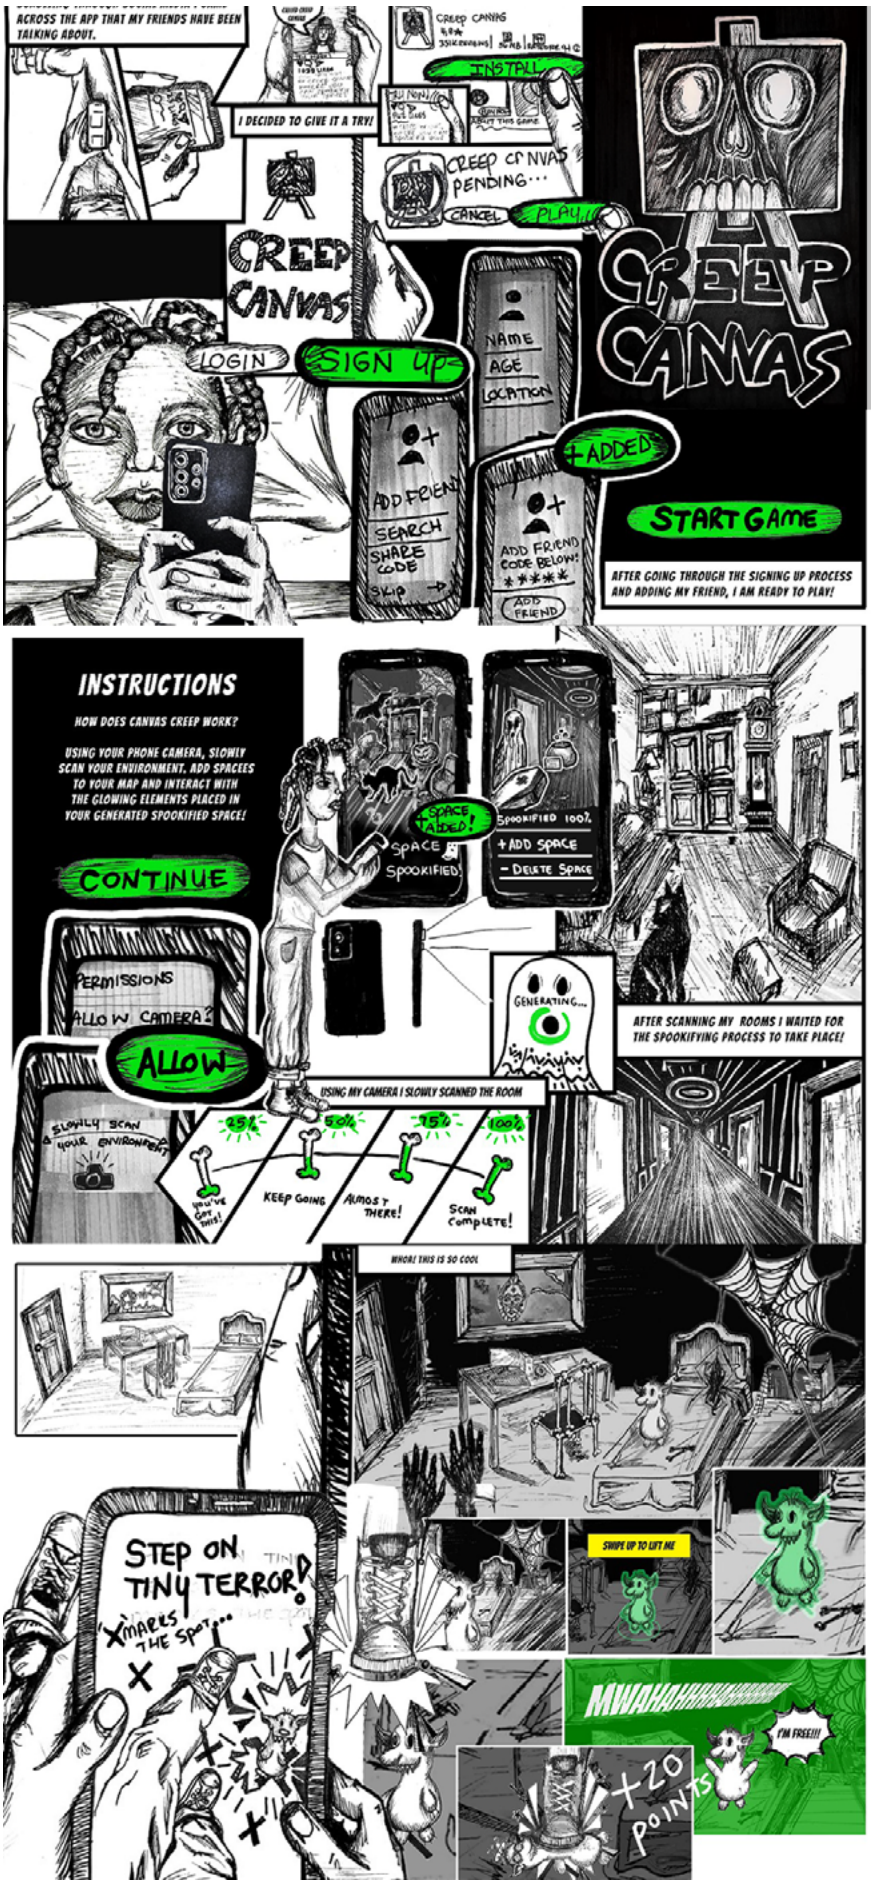

Figure 3. Example of a student group's final graphical design fiction (XRE comic) (Sarah Davis & Devorah Hodes, 2023).

6. Discussion

The discussion to follow draws upon the rich descriptions and reflections offered on the unit's enactment provided in the prior section, 5. The Design Process of the Teaching Unit. Three discussions will now be presented which, in line with the CDR methodology, have emerged through consideration of the criteria of Process, Relevance, Invention and Extensibility (Zimmerman et al. 2007, p. 499; Forlizzi et al. 2008, p. 27).

6.1 The Value of Narrative Design and Visualization in the Design of Concepts

When the design fiction storyboards, CJ maps and XRE comics are presented in the context of a process description they appear as stand-alone artefacts created in a fairly linear, step process towards a final design outcome: the XRE comic. This process narrative fails to capture two important aspects, or perhaps aspirations, of this teaching and research effort.

First, the role of the use of CJs should be understood and enacted towards enriching both the design fiction storyboard and visualization, not just the latter as the process suggests. Second, there is a particular way in which the DF narrative and the DF narrative visualisation aim to operate in relation to one-and-other both in their making and in what and how they communicate the final XRE concept.

Figure 4 provides an alternative to the process narrative by offering a visual description of the conceptual model intended for the construction of the XRE concept. In this view, both the storyboard (*1.1*) and the comic (*1.2*) are foregrounded and sit in connected relation to each other. The CJ map (*2*) is positioned as a background to both the storyboard and comic, while further acting in support of their relationship. Lastly, all three elements (*1.1*, *1.2* and *2*) are presented as parts which aim to constitute a whole larger than their sum, being the XRE Concept (*3*).

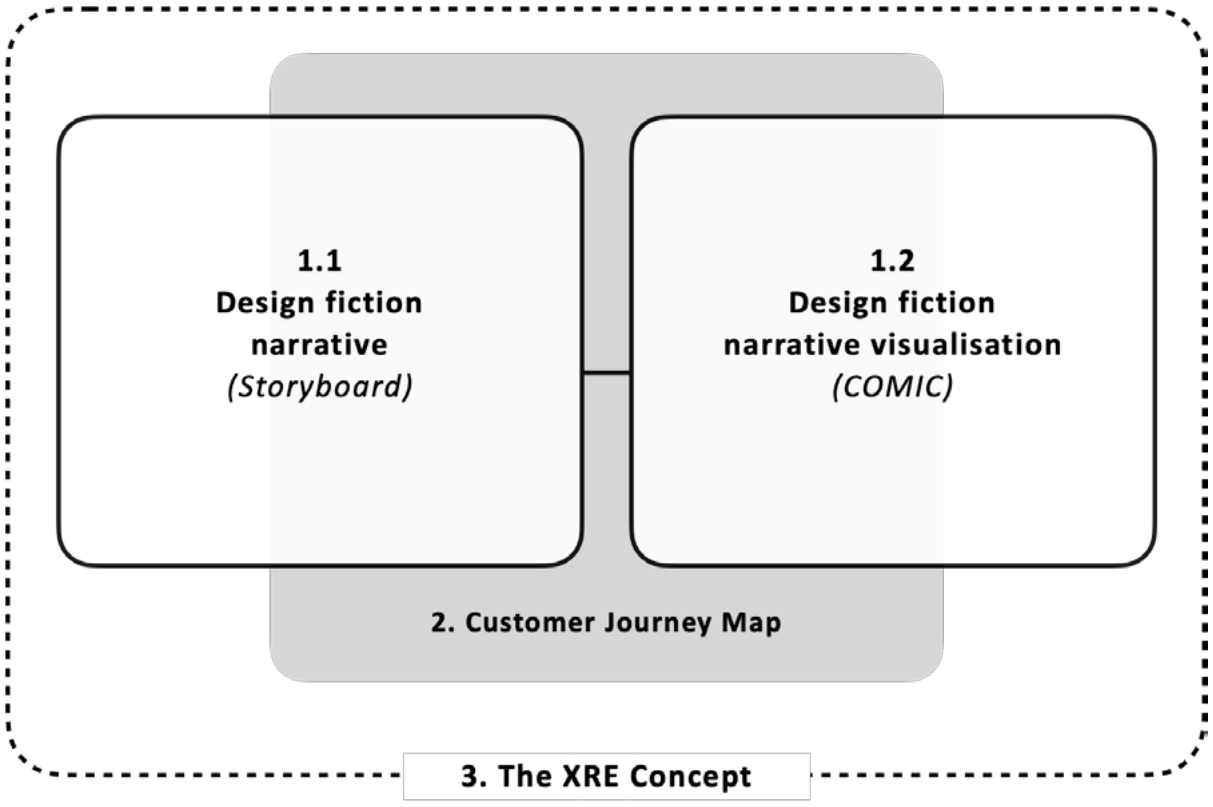

Figure 4. Conceptual model of the Extended Reality Experience Concept.

Although these parts were delivered at different stages in the process, they remained distinct deliverables required by the student assignment brief, and each received an equal weighting of 30% in the assessment criteria.9 As such, student's work produced over the course of the design project was graded as three equally weighted deliverables which, when tallied, constituted a grade given for their design of an XRE concept. Alternatively, if storyboarding and CJ mapping had been viewed as necessary activities, but ones which ultimately were throw-away aspects of the final deliverable (that is, the comic as XRE concept alone), then the weighting of the assessment criteria would have reflected as much.10

The reader will also have observed the introduction of a new set of terms to identify and describe the storyboard (1.1) and the comic (1.2) in Figure 4: Design Fiction Narrative and Design Fiction Narrative Visualisation, respectively. These terms denote a literal and functional relationship between two artefacts and / or two aspects required for the making and communicating of the XRE concept. Further understood as storyboard and comic, two individuated and very distinct kinds of artefact and forms of communication, force consideration and crafting of their relationship to support a mutual dependence towards a higher order of making.

This act of relabelling and (minor) distancing from a specification of artefact type, at least in the first instance and in the context of the conceptual model diagram, intends to open a door to a discussion and body of theory better suited to support the kind of relationship desired for the storyboard and comic in aid of concept design.11

Lastly, in this view, the CJ may come to be understood more deeply as a third part of a whole which allows for a broadened reach into solution possibilities at systemic 'scales' while also operating as a conceptual bridge between the DF narrative and the DF narrative visualisation. This becomes achievable without having to sacrifice the value to be found in a design object/product as an output of design in research and as research.

6.2 The Value of Design Fiction Graphic Narratives to the Communication of Systemic Solution Propositions

Reflecting upon the teaching engagement, a further insight regards the nature in which the graphic language of the comic narrative compliments and extends CJs. The foremost example of this is the ability of the artefactual presence of the graphic narrative to directly communicate the embedded role of the novel technology in the social fabric of peoples' lived experiences in a directly accessible manner. In contrast, the abstract schematic nature of the average customer journey can be unintuitive, particularly to a non-design audience. As such, graphic narratives allow for considerations of human experience, such as sensing, emotions, understandings, cultural dispositions, behaviours, and activities to be utilised as material in the creative process of design. From a pragmatic frame of reference, this allows for the meaning of the design to emerge through the communicated engagement between 'user-characters' and technological solutions. In this way, we argue, graphic narratives allow for designing with experiences rather than only designing for experiences. Tying these two concepts together, the relatable artefactual presence allows for the significance of the suggested experiences to be easily evaluated with audiences to ensure they resonate.

[9] The remaining 10% was reserved as a partial grade contribution for the timeous completion of a rough storyboard at the end of the Ideate Phase in week 1. The rationale being the necessary sequencing of the production of the storyboards, customer journey map and comic for the effective development of an XRE concept.

[10] For example, the storyboard and customer journey map could each have been weighted at 20% and the comic at 50%.

[11] The theory of 'message-content' and 'message-form' proposed by Tharpe and Tharpe (2018, p. 166) in their discussion of the design of concepts by way of objects, which intend to engage those with whom it encounters in critical dialogue over a particular subject matter or meta-discourse (Tharp & Tharp, 2018, p. 169) is the most likely candidate for future exploration given parallels observable between DF narrative and message-content, DF visualisation and message-form and their respective inter-relationships.

In a related point, the concreteness of graphic narratives, as opposed to the abstract nature of CJs, provides discursive positionality on how best to implement design strategy and tactics. By suggesting the application of these factors in 'real' world scenarios, these narratives prototype an approach that can be agreed upon, evaluated for impact, challenged, or discarded. Whether evaluating proposed experiences with target audiences and clients or within the design team, the value to testing the impact of solutions at a strategic level, prior to detailed product design, is of value.

6.3 The Value of Customer-Journey Thinking for Anticipatory Design Research Fiction

The application of CJs in anticipatory design research activities demonstrates a reciprocal value to that discussed in section 6.2. While CJs are well known to provide a method for the structuring of composite elements as a systemic response, they do so by foregrounding the designerly act of synthetically resolving that which is required to shift from what is, to what could be (Hobbs & Fenn, 2013, p. 200). From this perspective, CJs make visible the transformation of knowledge, facts and findings from prior research activities to futural narrative scenarios such that the 'synthetic integrity' of otherwise tacit strategic / design thinking may be interrogated by the traceability afforded by designing CJs (Ibid).12 Binding design fiction graphic narratives to an explicit and rigorous data-driven development of design strategy, as embodied in CJs, adds credibility to the design effort in general, and in particular, can help to negate any perception of conceptual weakness that might be implied by stand-alone graphic narratives.

7. Conclusion

This study explores, through teaching practice, how the converging theory and practices of UX and anticipatory design research can enhance an introductory XR teaching unit focused on the meshing of emerging technologies into the fabric of the human world. Through our experience of conceptualizing and teaching the unit, we discovered the following:

- Integrating CJs, and design fiction narratives in the form of storyboards and comics allow for highly structured, richly conceptualized and emotively communicated articulations of XR solution environments.
- Design fiction narrative visualisations are a powerful communicative modality for experience-led design.
- Design process associated with UX and service design, in which knowledge and facts are explicitly modelled into strategic design solutions, embodied in customer journeys, ensure design fiction narrative visualisations are based on rigorous research methods.

Looking to the future, again, since most of the research reported on, or generated herein, is derived from qualitative data capture, greater consideration of mixed methods designs would stand to extend and enrich the teaching and learner experiences, as well as the design work of students, the author's evaluation of course outcomes and possibly industry. Section 5. The Design Process of the Teaching Unit, in particular sub-sections 5.3. Process, 5.4. Outcomes and 5.5. Reflection on the Teaching, and all of Section 6. Discussion, relate.

Additionally, research in this area should include better understanding students experience of the course and more developed approaches for user-evaluation of their comics. Lastly, and on a somewhat practical note, in the next iteration of this unit, students will be exposed to the language and design of comics in a more formal manner.

[12] Also referred to as a 'Golden thread' by the authors (Hobbs & Fenn, 2013, p. 200)

KEYWORDS | SOUND NARRATION, ART INSTALLATION, CULTURAL HERITAGE LEARNING

ABSTRACT | In the realm of digital cultural communication within cultural tourism, visual experiences have traditionally held dominance. However, visual information overload can lead to issues including dispersion of user attention, comprehension difficulties, and constrained imagination. Sound possesses the capacity to enhance attention, cultivate an atmosphere, stimulate the imagination, facilitate deep thinking, and establish intimacy. Despite the potential of sound for cultural heritage communication, research on the impact of sound narration in cultural heritage learning is currently limited. Although some studies have confirmed that sound can enhance the learning experience of visitors at cultural sites, a comprehensive theoretical framework to encapsulate these effects has not yet been established. This study aims to investigate the effects of sound narration on cultural heritage learners through the design of a sound interactive installation based on the Changsha Kiln ceramics. Our aim is to systematically compile these impacts into a theoretical framework. The experiment utilized reflective sessions and observations as the primary data collection methods, based on text and interview data, primarily employing grounded theory for qualitative analysis and supplemented by bloom for quantitative research. Through a three-level coding process, the interview data were categorized into concepts and categories, leading to the proposal of a theoretical framework. The pilot results revealed that, regardless of qualitative or quantitative analysis, sound narration has a positive impact on learners of cultural heritage. We ultimately summarized the effects of sound narration on cultural heritage learners into a theoretical framework, encompassing perceptual, affective, conceptual, connecting, and strategic aspects.

1. Introduction

1.1 Current Research Status of Cultural Heritage Communication

Cultural heritage-themed exhibitions are essential in showcasing local culture, preserving collective memories, and integrating cultural experiences with tourism opportunities. With the advancement of digital technology and the rise of new media art, a growing number of exhibitions have begun to incorporate gaming elements, interactive installations, and immersive experiences. This fusion introduces innovative and interactive methods for experiencing cultural heritage. These innovative exhibition methods primarily utilize visual experiences for dissemination, such as *Virtual Reality* and *Augmented Reality* applications, developed and popularized within cultural heritage sites due to their entertainment and educational potential. Museums, serving as the main venues for cultural heritage exhibitions, create a visually demanding environment, where multiple exhibits, objects and displays compete for visual attention (Bitgood 2013). Visitors' visual attention is characterized by its fleeting and variable nature. The overload of visual information can result in distractions within user attention. Research indicates that sighted visitors often only glance briefly at individual exhibits or artworks, with the average dwell time being less than half a minute (Smith 2017). The majority of a user's gaze is directed towards the visual features and layout of the exhibit, whereas less consideration and understanding are given to deeper aspects such as the function and history of the exhibits. Visual elements inherently provide an intuitive representation, allowing users to grasp pictorial information through their visual senses without the need for imagination, thereby achieving the goal of understanding images. This characteristic partially impedes users' ability to reconstruct or creatively reinterpret images, curtailing their imaginative capacity. Anabela (2021) suggests that incorporating a multi-sensory experience, including the auditory, olfactory, tactile, and gustatory senses, in cultural heritage communication could inspire fresh perspectives and ideas, thereby leading to increased curiosity, exploration, and discovery among users. Despite the increasing trend towards multi-sensory experiences in museums, auditory remains overlooked. Less attention, less investment and very few infrastructures, human professional resources and less time are devoted to sound simulation, sound composition and sound design accompanying the visual narration in the field of cultural heritage and education. Underlying this refusal of museums is a somewhat unconscious distrust of sound, seen as a disturbing, uncontrollable, and unstable nuisance within the silent and reverential museum space, which was created for and by the objectifying gaze, particularly along visitor routes and in front of exhibits, where silence typically prevails. If present, museum staff tend to keep the volume so low as to be almost imperceptible. Considering the restrictions on museum visitation, sound can be delivered unidirectionally or multi-directionally through headphones in the context of cultural tourism or museum experience design.

1.2 The Advantages of Sound in Cultural Heritage Communication

Sound possesses significant and unique communicative abilities, and the experiential design of contemporary museums presents considerable potential for integrating sound. This article compiles the relevant advantages of sound in the dissemination of cultural heritage. (1) Sound can enhance user attention. Williams (2023) suggests that the delayed unveiling of an unseen sound source elicits suspense and tension, prompting users to focus on the exploration of reasoning and the construction of the full content of events. Although users have agency over visual imagery, allowing selective filtering of undesired content, the continuity of sound means users must passively accept all sounds, thus ensuring prolonged attention. (2) Sound can render atmosphere and evoke emotions. Cortez (2020) observes that sound is capable of creating specific atmospheres through soundscapes to evoke certain emotions and highlight thematic ambiance. Bertens (2019) has demonstrated that the use of sound in museums is able to stimulate visitors' emotional engagement. (3) Sound has the potential to stimulate users' imagination. Sighted participants viewed a series of photographs from *the Museum of London*'s collections presented in a digital format, and a comparison was made between the use of an audio descriptive guide (AGD), a traditional audio guide and visual exploration alone (Hutchinson and Eardley 2021). The study found that participants

who listened to an ADG when viewing photos demonstrated richer memories of the artworks. They not only recalled more visual details such as the content elements of the photos and their spatial arrangement, but also recorded more thoughts and emotional reactions to the artworks. (4) Sound possesses the capacity to stimulate profound reflective engagement among users. For instance, an ancient bridal headpiece designed with enlarged, spiky hair accessories, which a visitor would be invited to touch, manipulate, and wear. Embedded microphones within the headpiece emit a loud, piercing noise, prompting reflection among visitors. Ingold (2000) suggests that the purpose of the emergence of soundscape is not to represent, but to reveal, to penetrate beneath the surface of things in order to reach deeper levels of knowledge and understanding. (5) Sound can foster a sense of intimacy. Due to its directional nature, sound requires visitors to approach closely to the source. For example, Brackenbury (2023) crafted ceramic tiles into sound devices within a museum setting. When visitors pass through illuminated areas, directional speakers activate, and the tiles emit sounds narrating the stories of female artisans working in prisons. This proximity to the sound-emitting tiles subtly cultivates a sense of intimacy.

1.3 The Study of Existing Sounds in Cultural Heritage Education

Only recently have the acoustic properties of museum spaces or the acoustic horizons created by audio guides been discussed. A more comprehensive approach to the multifarious presence of sound in museums was published in 2019, in a special issue of curator: *The Museum Journal*, co-edited by Eric de visscher and Kathleen wiens. Turning to the application of sound in cultural heritage, the *The Sounding Object* project, a collaboration between the *Royal College of Art* (RCA) and *VARI*, showcased the immersive power of sound in cultural heritage. The project used sound design to critically engage with the museum's historical narratives. Additionally, Caroline devine's *Resonant Bodies* (2018) brings the sounds of a number of Indian classical instruments to life on the glass of their display case. The work was diffused using resonators attached to the case that made the glass surface vibrate with recordings of the sounds of the instruments—effectively acting as a giant speaker and allowing the instruments within the case to “Speak” to a visitor. This innovative use of sound not only enhanced visitor engagement but also fostered new connections with the audience. This research (Cortez 2022) resulted in the identification of five sound-based multi-modal museum practices, namely, 1. Sound as a mode for lecturing, 2. Sound as an artifact, 3. Sound as "Ambiance" or soundtrack, 4. Sound as art, 5. Sound as a mode for crowd-curation.

Despite the wealth of cases and innovative perspectives offered by existing research, research into the role of sound in cultural heritage learning is still limited, with an even smaller number of studies addressing the impact of sound narratives on the learning of cultural heritage. Hence, we are initiating a pilot exploration to examine the effects of sound narratives on cultural heritage learning, with the goal of developing a theoretical framework that encapsulates these impacts. This pilot exploration aims to offer insights and guidance for scholars and practitioners in the relevant fields.

2. Related Work

2.1 Sound and Narration

Sound possesses a unique narrative function, serving to represent and narrate aspects of artistic conception, characters, and plots. Language, sound effects, and music constitute the three core elements of sound narration. For instance, in the sound narrative of *A Man Escaped*, language not only conveys explicit semantics but also intricately links storylines and vividly depicts character images. Sound effects extend the visual space, represent character psychology, and enhance environmental realism. Music propels plot development, communicates character emotions, and acts as a metaphor. Gopalan (2017) emphasizes that employing rich layers of ambient sound in narrative strategies can create an immersive sense of realism. For instance, In *The National Treasure*, the artifacts' southward migration is compellingly narrated using multi-layered ambient sounds—bombings, car crashes, fires—thereby enriching the introduction of the *Stone Drum* in the museum's collection. The advancement of sound narration necessitates an understanding of

specific cultural backgrounds, thus unavoidably embodying national cultures. For example, *Night Banquet in Tang Dynasty* merges virtual scenes with real stages through *5G+AR* digital technology, where sound narration carries the national spirit and culture, eliciting a sense of national emotional resonance among the audience, strengthening cultural identity, and thereby facilitating cultural dissemination and enhancing cultural confidence.

2.2 Sound Narration in Cultural Heritage

In recent years, numerous curators have shifted their focus towards the development of multi-sensory exhibitions, with a particular emphasis on auditory experiences. For instance, the sonic cultural artifact, *Diabolo*, is depicted in the *Beijing local chronicles* as producing sounds that are “As resonant as a bell and as delicate as the flutter of an insect's wings”. The sonic heritage encompasses a variety of traditions, significant sounds, music, individual instrumental or vocal techniques, and soundscapes. However, current exhibitions primarily focuses on the display of tangible objects and images, overlooking the perception of sound within cultural heritage. This neglect of sound representation can lead to a gradual erosion of sound folklore. In the realm of cultural heritage and the dissemination of sound, sound categorization encompasses multi-character sounds, cultural heritage sounds, and environmental ambiance sounds. For instance, the sound narrative in *China in Classics* employs a multi-layered sound source including vocal language, background music, and acoustic scenes. This enriched sound quality enhances the listener's imaginative space and conveys deeper connotations. Michalis (2023) has designed a context-aware audio guides tailored to the actions and interests of museum visitors. These systems make use of wearable cameras and advanced machine vision algorithms, enabling real-time recognition of scenes and inference of context. In the realm of *Audio Augmented Reality* (AAR) applications, the exhibits themselves become narrators, emitting sounds or telling stories in the first person. This approach not only reveals "Hidden" sounds within the environment but also significantly enriches the visiting experience. Moreover, it affords users the opportunity to physically interact with the exhibits. Despite considerable expectations, the application of sound narration in the preservation and interpretation of cultural heritage is still limited, with a lack of comprehensive research into its effects on learners of cultural heritage.

In this study, we will systematically review and analyze the latest research on sound narration and installation design. The purpose of this pilot study is to explore the potential positive impacts of sound narration in art installations on learners of cultural heritage. We aims to summarize the theoretical framework regarding the effects of sound narration on cultural heritage learners and provide an initial theoretical basis and reference recommendations for other researchers involved in the design of cultural heritage-related learning.

3. Research Methods

3.1 Designing a Ceramic Art Installation

This pilot exploration is based on the design of a series of sound interactive installations centered around the ceramic culture of Changsha Kiln in china. It aims to study the process of visiting and learning experiences of cultural heritage learners within exhibition halls. Art installations refer to conceptual frameworks or digital environments created by artists (Giulio 2016), which invite participants to explore and experience. Through interaction, participants are encouraged to discover, interpret, and reflect on the meanings of the installation and its components, thereby establishing a connection with the installation throughout the experiential process. Changsha Kiln ware was one of the primary commodities along the maritime silk road during *the Tang Dynasty,* embodying a unique style that integrates eastern and western cultures. We have selected iconic items from different stages for abstract design, incorporating metaphorical features such as scratches on the surface to provide users with ample room for imagination. To facilitate a "Dialogue" between visitors and the historical craft behind the culture, we embedded a speaker inside the ceramic items and used the ceramic space as a mini sound field to emit sounds. Please refer to figure 1 for

details. The sound and touch systems were developed using *Arduino* software (a professional programming platform). The four ceramic installations are arranged in chronological order, each representing a different development period. Initially, users are required to touch the sensors located on both sides of the ceramic object simultaneously, triggering brief sound clips of craftsmanship, as if ancient artisans were demonstrating their skills right in front of the users. These four sets of ceramic audio correspond to the manufacturing states of the four objects, as illustrated in figure 1. Subsequently, by touching the sensors on the ceramic objects again, users can listen to sound narratives in which the ceramics "Reveal" their mysterious origins, conveying knowledge about history, culture, and craftsmanship in the first person. We utilize multi-character narratives, cultural craftsmanship sounds, and environmental ambient effects to strengthen the connection between users and historical culture. Tactile feedback upon touching the body or handle of the ceramics enriches users' perception of the ceramics, thereby creating a tangible cultural experience as if users are shaking hands with history through time and space. Meanwhile, visual cues such as background information and introductions are projected onto a sailboat backdrop using a projector, as shown in figure 2. This pilot study aims to explore the influence of sound narrative on cultural heritage learners and to develop a theoretical framework informed by the findings.

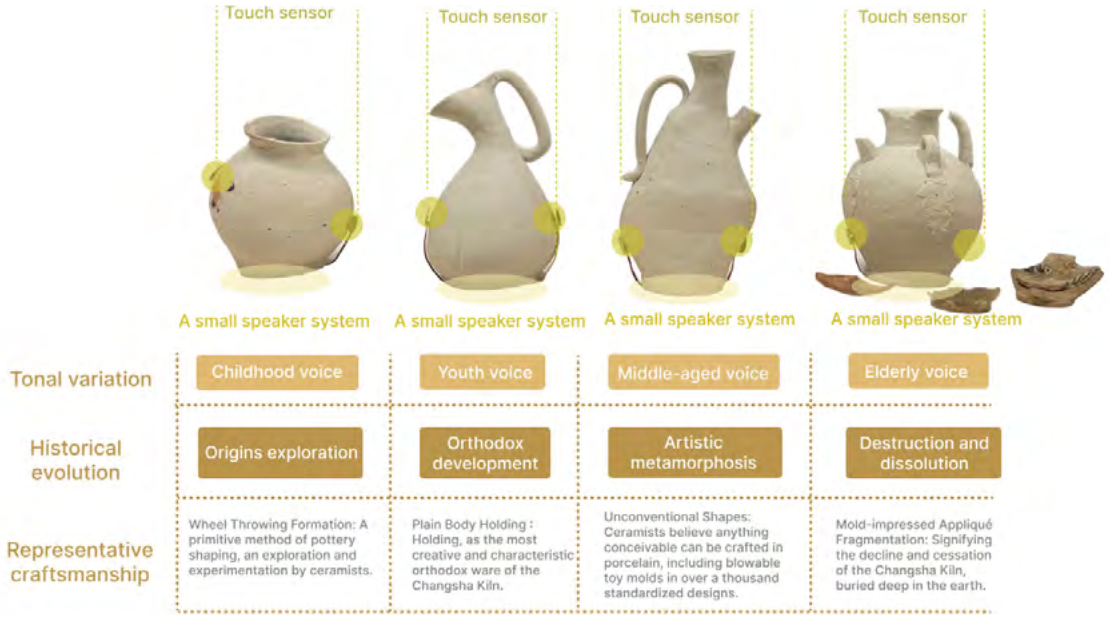

Figure 1. Functional interaction diagram of the art installation.

Figure 2. Experimental setup overview.

3.2 The Experimental Procedure

Our experiment spanned 8 days, encompassing a pre-experiment phase, a formal experiment, and a reflective session. Participants were recruited through advertisements in school general education courses and social groups, ranging in age from 18 to 32 years (median age: 24 years), totaling 68 university students (30 males, 38 females). The experiment was randomly divided into two groups: an experimental group that utilized a sound installation (33 participants) and a control group that engaged with paper materials (35 participants), with each group conducting experiments for an average duration of one hour. The experimental procedure was structured into three modules. In the "Narration about ceramic sounds" module, participants were guided to contemplate the origins of four sounds from the pottery-making process. The "Voices about ceramics" module aimed to assist participants in purposefully seeking answers, revealing how the initial sounds were produced and enhancing their understanding of Changsha Kiln culture through sound narratives. In the "Collaborative narration" module, participants acted as narrators for the Changsha Kiln, working in groups of 2-3 to review and assess the learning outcomes. Images, served as the dependent variable, were displayed via PPT projection. For the control group, the task process remained unchanged, except that all auditory materials were converted into paper materials for reading purposes. The task process for the experimental group is depicted in figure 4.

Figure 3. Experimental group (sound narration) on the left and control group (text reading) on the right.

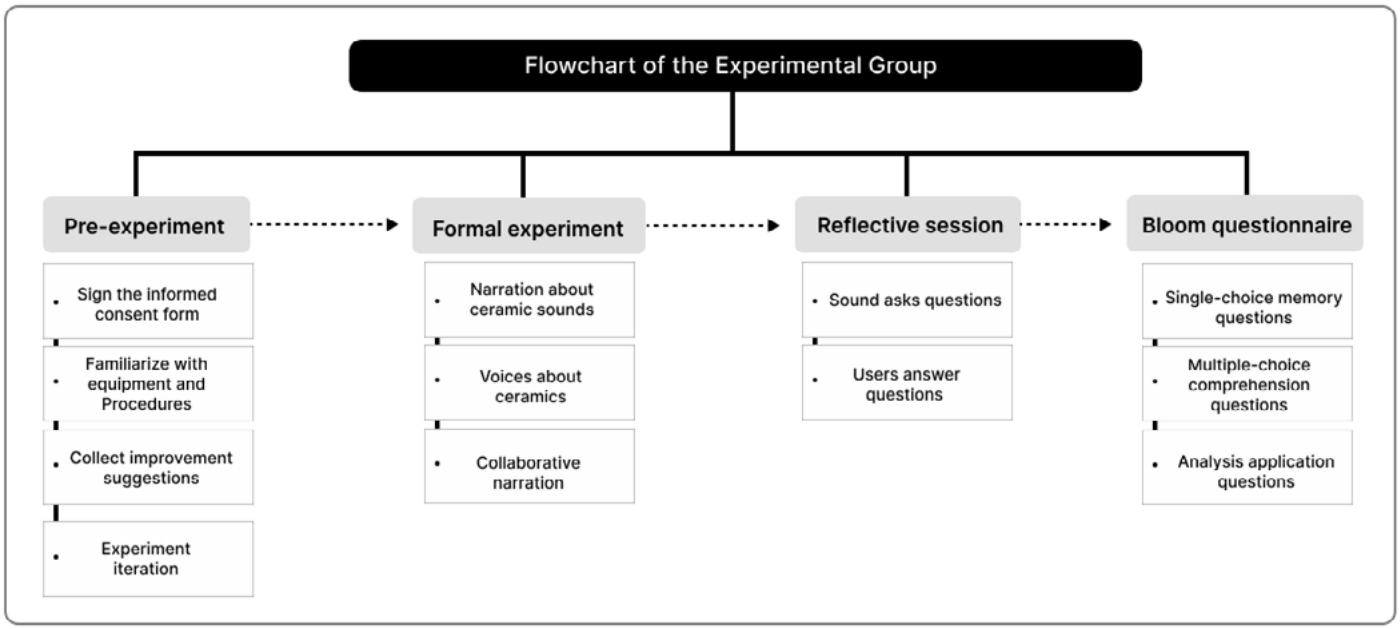

Figure 4. Flowchart depicting the procedure for the experimental group.

Pre-experiment

Initially, participants are provided with a concise overview of the process of this pilot study and invited to sign the paper informed consent form. Researchers offer concise oral instructions to familiarize participants with the equipment. Subsequently, participants engage in the experiment, evaluating the design process and compiling suggestions for enhancements, which leads to iterative modifications of the experiment. Following the pre-experiment phase, participants are required to complete a questionnaire that includes bloom's learning effectiveness assessment and an evaluation of the sound interaction device.

Formal experiment

(1) Stage 1: Narration about ceramic sounds

The sounds encapsulate the quintessential craftsmanship scenes of the Changsha Kiln. At this stage, the installation presents four sets of sound experiences associated with the Changsha Kiln's production process: the kneading of clay, the thudding sound of clay manipulation; the sound of bisque immersion in glaze, the clink of object collisions. The roar of the fiery blaze, the crackle of porcelain fissuring. The shatter of ceramics, the sound of sweeping porcelain shards. The sounds correspond to four states of the objects in the installation. Upon user activation of the sensor, the four sets of sounds are played sequentially. After the sounds end, participants are engaged in a reflective session with structured inquiries such as "What sounds did you hear?" and "What associations did these sounds conjure?"

(2) Stage 2: Voices about ceramics

This study delineates four developmental stages of the Changsha Kiln, each narrated through distinct vocal tones corresponding to different life stages (child, youth, middle-aged, elderly) to represent the kiln's evolution. These vocal tones symbolize the kiln's evolutionary stages. Adhering to Lissa's (2016) recommendation, a first-person narrative approach was employed to enhance emotional engagement and comprehension among the audience, thereby potentially augmenting their learning experience. The sound narration is methodically segmented into three explanatory layers to improve content coherence: (a) Appearance, which includes the form properties of Changsha Kiln artifacts, such as material, decorative patterns, and shapes. (b) Craftsmanship, which includes the techniques and production methods used in the ceramic creation of Changsha Kiln, such as under-glaze painting, applique (applique involves adding low relief clay forms to slurred, scored leather-hard surfaces for embellishment). (c) Culture, which includes the local culture activities related to ceramic production in the Changsha Kiln, such as kiln workers in the *Tang Dynasty* used advertising slogans as characteristic decorations. Complementing the sound narrative, projected visuals and textual descriptions aid users in comprehending the narrative content. The second interaction with the installation's sensor is designed for users to further explore the narrative. For example, initially, users experience the sound of shattering, and in a subsequent round, the sound narrative elucidates the reasons behind the disrupted firing process of the Changsha Kiln. This approach of posing questions and seeking answers through a progressive auditory experience can subtly facilitate users in acquiring knowledge related to the Changsha Kiln. Interview questions include: "Please recall and describe its production" and "What were the most impactful aspects of the sound narrative?"

(3) Stage 3: Collaborative narration

We invite 20 groups of users, each comprising 2-3 individuals, to engage in collaborative narration based on their newly acquired knowledge of Changsha Kiln. Participants are encouraged to adapt, reconstruct, or share the learned content, aiming for a collective narration of a complete story. This method enhances memory retention and clarity for all participants, creating a unified narrative thread and fostering a sense of achievement through team performance. Collaborative narration between two people combines the benefits of cooperative discussion while avoiding the confusion and distractions common in larger groups. It also allows sufficient time for free expression, especially when opinions diverge. Gurtner (2010) notes that individuals differ in their perspectives and focal points in information reception, suggesting that through

mutual complementation, effective cognitive regulation can be achieved, thereby establishing an interdependent learning network.

Reflective session

Participants were invited to partake in semi-structured interviews aimed at delving into their creative conceptualization process and addressing any uncertainties they encountered throughout the process. Reflective interviews encourage users to engage in deeper thought beyond their initial responses that come to mind, for instance, by asking participants to provide reasons or explanations for their actions or occurrences during the interaction. Finally, participants were required to complete a learning assessment questionnaire, devised in accordance with bloom's taxonomy, encompassing single-choice memory items, multiple-choice comprehension items, and analytical application items. Upon the conclusion of the experiment, three experts were invited to evaluate the learning outcomes and related impacts through both qualitative and quantitative methods.

3.3 Experimental Method

In this study, we employed a combination of methods for data collection and analysis. In the pre-experiment phase, semi-structured interviews were primarily used to collect user feedback and opinions, facilitating adjustments to the experimental design while also acquainting users with the experimental process. Upon completion of the experiment, we primarily conducted reflective interviews to collect primary data. This was supplemented by observational methods to document alterations in participants' facial expressions, movements, and behaviors. At the experiment's conclusion, a reflective session was conducted to prompt participants' engagement in reflective thinking and assessment of their learning outcomes.

Our data collection is predominantly achieved through reflective interviews. Posing reflective questions assists users in understanding and articulating their latent needs and goals. Following Atkins (2018) three stages of reflection: noticing, understanding, and planning future actions, we crafted a sequence of sound-based prompts for questioning followed by user responses. By asking "Why" twice, we introduce reflection touch-points, prompting users to take additional time for contemplation and response. Data were collected using a variety of methods, encompassing observation, written and oral responses, surveys, in-depth interviews, stimulus recall exercises, and dialogic interactions.

Our data analysis is based on grounded theory, a qualitative methodology introduced by Glaser and Strauss, is a qualitative method that aims to develop a theory grounded in the data collected. This method emphasizes identifying core concepts within the data, summarizing these, and utilizing coding procedures to construct a theoretical framework. The coding process unfolds in three distinct stages: open coding, axial coding, and selective coding, facilitating a structured analysis. Through the application of *NVIVO* software for analysis, we initially dissected and organized the interview content into over 6,000 original sentences. We extracted high-frequency words, categorizing them into 95 concepts and 27 distinct categories. In the process of axial coding, categories were reclassified based on their logical relationships, leading to the development of primary and secondary categories. Subsequently, during selective coding, all categories were interconnected and integrated, clarifying the relationship between core and main categories through specific cues. The preliminary establishment of a mechanism model for the impact of sound narration on cultural heritage learning. To ensure the objectivity and accuracy of the coding results, we randomly selected 18 participants for interviews as a sample for saturation testing. The coding analysis did not reveal any new concepts or categories, indicating that the conceptual model constructed in this study is theoretically saturated. Ultimately, the effectiveness of user learning was quantitatively assessed using bloom's taxonomy, objectively evaluating different groups of users on their retention of knowledge, comprehension, and application through a written test.

4. Result and Discussion

This study based on textual and interview data, primarily employs grounded theory for qualitative analysis and supplemented it with bloom questionnaire for quantitative research. Through a three-level coding process, the interview data were categorized into concepts and categories, leading to the proposal of a theoretical framework. The pilot results revealed that, regardless of qualitative or quantitative analysis, sound narration has a positive impact on learners of cultural heritage. This framework encompasses five core concepts: perceptual, affective, conceptual, connecting, and strategic, as shown in table 1 and figure 5.

Table 1. Coding analysis of the impact of sound narrative on cultural heritage learners.

Categorization	Categorization	Conceptualization	Connotation
Perceptual	Auditory perception	Sound immersion...	User sound perception and cognition
	Tactile perception	Close-range tactile interaction...	User tactile perception and cognition
	Immersion(objective)	Sense of engagement...	Feeling of immersion during interaction
	Presence(subjective)	Immersed in descriptive setting...	Feeling of being in the described situation
	Curiosity	Reason for curiosity...	Curious or questionable content
	Attention	Point of attraction...	Attention-grabbing aspects
	Memory	Short-term memory...	Users' memory of what they hear
	Quotation	Famous quotes and sayings...	Exact quotation or approximate paraphrase
	Identification	Recognizing sound changes...	Point out things that need attention
	Characteristic	Characteristics of exhibits...	Say the content and other characteristics
	Understand	Deeper understanding...	Understand certain reasons, principles.
	Learning ability	Active learning..	Learning methods, content mastery.
	Retelling ability	Retelling interest...	The ability to retell and express the process
Affective	Emotional understanding	Emotion perception...	understanding of character emotions
	Emotional expression	Confusion; shock...	Emotional expression in face/body posture
	Emotional regulation	Emotional adjustment...	Reframe emotional emotions
Conceptual	Simple reasoning	Inference part connection...	A single analysis or interpretation section
	Complex reasoning	To make assumptions...	Deep inference or system overview
	Ability to predict	Predict the plot...	Predict what's going to happen
	Ability to reflect	Reflect on current cognition...	Reflect on yourself currently or in the past
Connecting	Life-connection	Personal experience connection...	Contact personal life analogy comparison
	Knowledge-connection	Contact history...	Think of existing knowledge
	Inter-exhibit connection	Exhibit contact...	Connect elements between different exhibits
Strategic	Use	How to find the answer...	For device usage procedures
	Sharing	Share understanding;...	Share knowledge,encourage others to participate
	Performance	Body affirmation...	Evaluate performance when working together

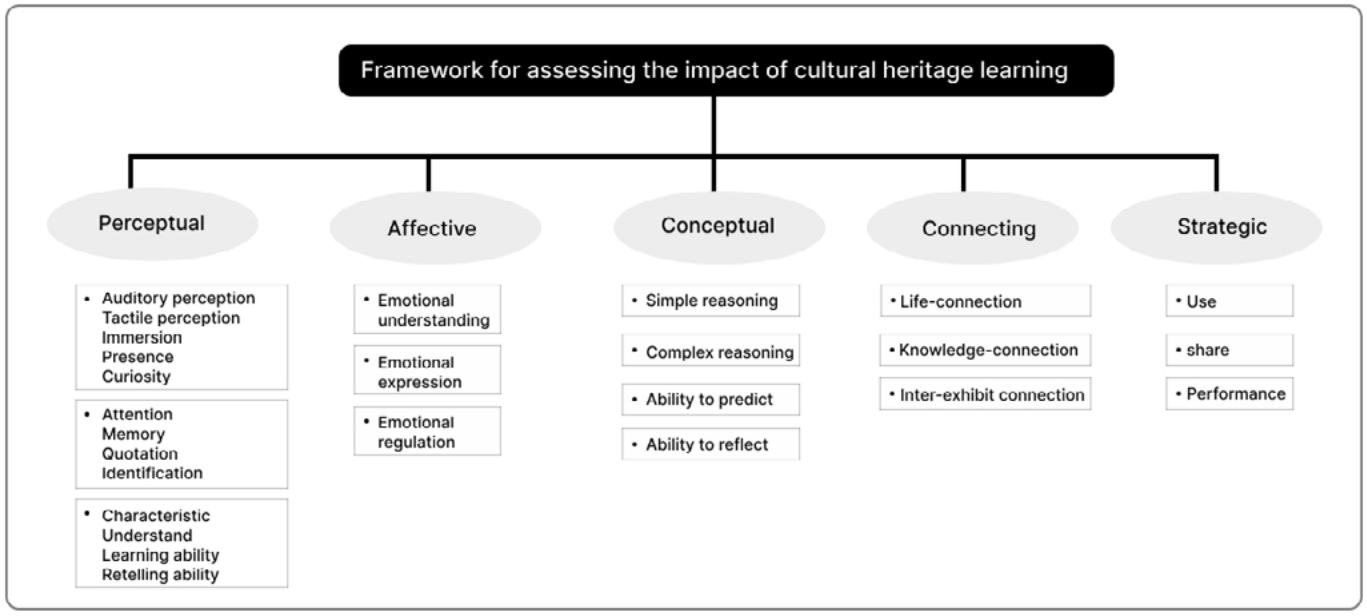

Figure 5. Theoretical framework of the impact of sound narration on cultural heritage learners.

4.1 Perceptual

This category encompasses discussions related to participants identifying elements within their environment. Allen (2002) posits that when users pinpoint and share essential content in complex settings, it denotes learning. This behavior is considered indicative of learning, as it involves recognizing and communicating significant elements in a complex environment. The category is subdivided into areas such as auditory perception, where the user acknowledges the perception and cognition of specific sound content, for example, "The sound conveys a sense of historical ambiance." Tactile perception involves users discussing perception and cognition related to touch, such as "Touching artifacts up close feels as though they are narrating a story." Immersion is experienced when interacting with artifacts, creating a sense of being transported and immersed in the experience, illustrated by "The sound narration engenders a sense of immersion." Presence refers to the user expressing a subjective feeling of being immersed in the described setting, stating, "It feels as if I have truly entered a war-torn era, embodying a pottery jar and sensing the urgency of their escape." Curiosity is manifested when the user expresses curiosity or doubt, with questions like "Why did it break? was it because of a tradition? I have heard about the tradition of breaking pottery before." Attention is drawn to elements that capture attention during interactive experiences, for instance, "This tone is very pleasing", "I would love to keep listening." Memory involves the user's recollection of the content, with comments such as "I remembered all the key details very clearly." Quotation includes accurate quoting or close paraphrasing during the user experience, as in "During the prosperous cultural period of the Tang Dynasty, emissaries from eight nations paid tribute." Identification occurs when the user highlights something noteworthy, for example, "The deep and resonant sound also symbolizes power and authority." Characteristic involves the user describing features of the exhibit, sound, narrative content, saying, "The sound also represents the growth of history, making it clearer and more enjoyable to listen to." Understanding is the user grasping certain reasons or principles, mentioned as, "It is easy to understand." Learning ability refers to the user learning through interaction and gaining insight into the learning process, as in "It naturally expands my knowledge." Finally, retelling ability is the user's performance in recounting, for example, "There is a master craftsman named Wang Er who has purchased a kiln factory..."

What sound narration enhances is auditory perception, tactile perception, immersion, and presence experience. Abundant sound variations and interesting narrative content attract participants. They describe it as "Immersing oneself in the experience of listening to stories." Coffey (2023) indicates that the immersion process can maintain learners' interest and motivation, leading to increased engagement, better understanding of the learning material, greater persistence, and increased resistance to potential obstacles. It was found that the participants in the experimental group exhibited stronger attention and curiosity

compared to the control group. They displayed greater patience in exploring the reasons behind the generation of sound. Compared to the control group, the experimental group demonstrated a higher ability to incorporate quotations. For example, in the case of the Changsha Kiln firing incident, 82% of the participants used historical allusions or famous quotes to express their sadness, such as "No member escapes unscathed from a family disaster." After listening to the sound narration, nearly 67% of the users were able to infer historical changes by recognizing changes in tone or the characteristic features of objects. For example, they identified that "The pottery changed from weakness to triumph and then declined" or that "The sound implied destiny." Sound narration can stimulate users' active learning and enhance memory. 88% of the participants in the experimental group actively asked more questions during the recall interviews, such as "Does the gender of the sound affect people's associative effects? are there women among the kiln workers?" Results from the bloom's taxonomy-based questionnaire indicated that the experimental group achieved higher memory scores, with the experimental group achieving an accuracy rate of 80%, the control group had an accuracy rate of 70%. However, from the interviews and questionnaires, it was observed that the two groups had different memory preferences. The control group focused more on the product's appearance and craftsmanship, whereas the experimental group placed greater emphasis on cultural stories, particularly regarding customs and historical narratives. The bloom questionnaire revealed that the experimental group demonstrated superior performance in the dimensions of comprehension and analysis, enabling them to draw connections among political, economic, and cultural contexts, and to elucidate the interrelations among these aspects. For instance, one participant cited *The An Shi Rebellion* as an illustrative example. Furthermore, we also found that experimental group users showed high confidence in the events described in the sound narration, such as "Although i'm not familiar with history, i am certain about how the sound is produced." The study suggests that sound can evoke a rich imagination and enhance users' comprehension abilities. They also demonstrated a more complete and logical retelling of the story during collaborative narration, while incorporating more historical references. In conclusion, the findings suggest that sound narration significantly improves participants' ability to retell stories, incorporating a richer array of historical references.

4.2 Affective

This category encompasses user emotions, including emotion understanding, emotion expression, and emotion regulation. Emotion understanding involves comprehending character emotions, as exemplified by statements such as "I sense a sadness akin to that of a kiln worker," while emotion expression refers to how emotions are conveyed through facial expressions or body language, such as users frowning, smiling, or appearing contemplative, and emotion regulation concerns adjusting emotions, as demonstrated when someone states "Initially proud of the era's technology, the outbreak of war and the potters' demise led me to reassess my feelings."

Two caveats merit attention regarding the "Affective talk" category. First, verbal measures serve as crude indicators of an exhibition's emotional impact at best. Capturing affective learning talk is valuable, and we believe that capturing the use of emotional words in conversations is a key aspect of reflecting users' emotional engagement. Roberts (1990) provides a comprehensive review of alternative methodologies for understanding affect. Second, visitors' expressions of displeasure do not inherently critique the exhibition. For example, although the sound of robbers smashing objects and harming kiln workers may elicit feelings of anger and sadness, it simultaneously deeply engages visitors and may even evoke a sense of immersion. 82% of the experimental group acknowledged that the sound enhanced their understanding of the emotional dimensions and historical context, fostering deeper reflection and a more nuanced comprehension. They demonstrated a more nuanced understanding and expression of emotions, for instance, deeply sensing the brutality of war and the powerlessness of the lower-class people through sound. In contrast, control group participants were more reserved, with some struggling to focus on the text and overlooking details they were not inclined to explore. They also noted the advantage of text in controlling reading pace. The bloom questionnaire revealed differences in expression between the two groups. The experimental group utilized more emotional and descriptive language in analyzing the questions, such as "The tiny monkey cuddling its mother, creating a highly heartwarming scene," while the control group used more precise vocabulary closely aligned with the text provided, for example,

"The techniques and production methods used in the ceramic creation of Changsha Kiln, such as under-glaze painting."

4.3 Conceptual

This category pertains to the cognitive interpretation by users of items they find intriguing within the exhibition. Discussions should not necessarily be abstract but ought to involve multiple steps and lead to insightful conclusions. The active construction of new knowledge is essential in the learning of cultural heritage. For instance, the experimental group asked additional questions to deepen their understanding of cultural heritage. The subcategories of conceptual talk include simple inference, which is an interpretive statement or interpretation of part of an exhibit. For example, "During the prosperous Tang Dynasty, people loved writing poetry, which they incorporated as decorations on ceramics." Complex inference involves generalizing exhibit information, formulating hypotheses, or discussing the relationship between objects or their properties. An example is "The item serves not only a functional purpose but also as a means for craftsmen to express their ideas through its shape, conveying their thoughts and memories." Prediction refers to an expectation of future events, including what visitors are about to see or do. For instance, "The Changsha Kiln culture is expected to regain prominence in public interest." Reflection involves considering one's current or previous state of knowledge, like "What inspired me is the idea of adding olfactory interaction to sound and tactile interactions."

Upon analyzing the discussions triggered by exhibition elements, we observed no significant differences between the experimental and control groups regarding simple inference and prediction. However, the experimental group demonstrated more profound and systematic conclusions in their complex inferences. Notably, 86% of its members discussed three or more dimensions, including "Policy," "Diplomacy," "National culture," "Writing," "Poetry," and "Ethnic minorities." In their reflections, the experimental group excelled in their mentions of "Future," "Self," "History," and "The fate of the people," totaling 26 times. They also contemplated the more effective application of their disciplinary knowledge (History, Ournalism, Design) in their future professional endeavors, discussing this application 14 times. Notably, a design student expressed an intention to explore the olfactory aspects of cultural heritage in future studies.

4.4 Connecting

This category focuses on the dialogue where users integrate cognitive aspects of an exhibition with their existing knowledge and experiences. Exhibits serve as catalysts for sharing personal stories or previously acquired information, marking a significant part of learning. The three subcategories include life-connection, knowledge-connection, and inter-exhibit connection. Life-connection involves making personal associations, likening elements of the exhibit to familiar experiences. For example, one might say, "This reminds me of the audio-books I read before, the male protagonist's voice captivates me." Knowledge-connection is about expressing prior knowledge, such as identifying a historical period of turmoil. Inter-exhibit connection involves drawing links between different elements of the exhibit, akin to comparing artifacts to the relationship between a father and son.

During our experimental process, we discovered that all instances of learning-related dialogue involved some degree of prior knowledge. This suggests that specific elements within the exhibition served as catalysts, prompting participants to recall additional knowledge or past experiences. In the experimental group, 82% of participants explicitly linked their observations to various knowledge domains, such as "Geography," "Diplomacy," and "Economics" actively drawing comparisons between exhibition elements and familiar concepts. Furthermore, 62% of these users referenced their past visitation experiences during discussions, linking them to previous learning encounters. Reflective interviews revealed that visitors in the experimental group were more actively engaged in sharing personal stories or previously acquired information, even when these narratives were not directly related to their current observations.

4.5 Strategic

This category captures the collective discussions and behavioral dynamics through which participants strategically engage with exhibits to co-create narratives. Use provides guidance on how to interact with exhibits. An example is instructions such as "Touch it like this to produce sound," which facilitate interactive engagement. Sharing which involves the dissemination of knowledge and the encouragement of participation, illustrated by invitations like "I'd like to share a topic with you." This subcategory emphasizes the importance of knowledge exchange and collaborative learning. Performance focuses on evaluating collaborative efforts, as seen when two participants acknowledge their agreement in a discussion through a congratulatory gesture, such as "High-five". By examining these subcategories, the study aims to understand the nuanced ways in which participants interact with the exhibition to collectively construct narratives and share knowledge.

Sound narration enhances interactive communication among visitors through use, sharing, and expression. The experimental group engaged more deeply, evidenced by longer viewing times and more frequent stops at exhibits. Notably, 85% of participants in the experimental group actively participated in discussions, especially during pauses by their interlocutors. They demonstrated increased physical engagement, including hand clapping, smiling, leaning forward, nodding, and arm crossing. They also offered verbal support, using phrases like "Yes, i agree," "I feel the same," and "Me too." We conclude that sound narration enhances learning, communication, and discussion among visitors. Cortez (2022) posits that sound can foster a highly social environment, encouraging dialogue and engagement. In contrast, visitors in the control group engaged in brief discussions, focusing on narrative elements or factual information without detailed explanations of their choices. They also showed a lower frequency of interactive behaviors and expressions.

5. Conclusion

This pilot exploration investigates the impact and potential of sound narration in the context of cultural heritage learning through a sound interactive ceramic installation based on Changsha Kiln. Sound narration serves to extend the history presented by the exhibits and establish new connections between visitors and cultural heritage. The results of the pilot study indicate that both qualitative and quantitative studies can validate the positive impact of sound narration on cultural heritage learners, influencing them in terms of perceptual, affective, conceptual, connecting, and strategic aspects. One limitation of this pilot study is the limited output of content from the corpus. We plan to integrate with artificial intelligence dialogue systems in the future to provide users with more detailed and accurate answers. Overall, the evaluation of the art installation experience was considered effective.

KEYWORDS | PRINT INTERACTION, INTERACTION DESIGN, INTERACTIVE PRINT MEDIA

ABSTRACT | Interaction design focuses on the creation of digital and physical products that enable users to interact with media and technology in intuitive and meaningful ways. While it has traditionally been associated with digital screen-based interfaces, recent advances in printed electronics and paper-based media allow interaction with information on traditional media related to print industry and visual design. This, along with the willingness to understand behavior in print media, as an additional element in visual design, and a consequent need to identify the knowledge involved and how it can be articulated in a single design project, sets the stage for a new design space. There are several hints and notes that can be used to portray print interaction design as a new design space, drawing on relevant literature, observed cases and design experiments. I elaborate and discuss on the notions of physical/digital interaction and tangible interfaces with the idea of transposing interaction elements to traditional media, arguing that print media have an interactive ability, which can be considered at the time of their design and, consequently, of being produced to offer diversified experiences, maintaining cognitive and haptic advantages. An explanation and systematization of the main points is provided, which could lead to the definition of a design space for interactive print media, as grounded on existing information and material and technological possibilities. The result understanding will be relevant for design projects involving print media and for future research about the materiality of interactive systems.

1. Introduction

When we think of print media, we remember reading a book on vacation, studying from textbooks, flipping through magazine or newspaper pages looking for news, consulting product or museum catalogues, receiving letters from various companies. We think of static, unalterable objects, with no possibility to be modified by people who use them. Those who produce such objects follow an established process of material production, in order to adapt to expectations of use and circulation. Those who conceive them respond to communication requests, which are more influenced by commercial pressure and which turns these media into objects of attention and work by designers and marketers. As we have found digital equivalents for most of these media, they have come down in terms of circulation, sale or use. Their replacement brings, in some cases, material optimization or immediate updating, but it can also generate difficulties in learning, interpretation, access to knowledge, cognitive development and well-being.

I argue that print media have an interactive ability, which can be considered at the time of their design and, consequently, of being produced and made available to offer diversified experiences, maintaining cognitive and haptic advantages and contributing to reduce print media disappearance and the economic impact it creates on several sectors of human activity.

Interaction can work as a positive feature since it has expanded to a spectrum of physical and hybrid situations. This places the concept of interaction as extendable to print media and also resulted in some experimental technological-driven prototypes, where print media became available for transformations, using flexible displays, foldable interfaces, E-ink displays, conductive sensors and conductive ink. These prototypes show variables not yet considered in print media and reveal a proximity of areas of knowledge and practical activity, which allow us to anticipate the creation of a specific design space.

From the report of these cases, a few hints are highlighted that suggest aggregating characteristics for them. I elaborate on these hints, discussing partial and specific contributions that certain areas of design can make and I present some notes, which can lead us to the definition of print interaction design as a new design space.

2. The Transition of Print

Print media are conceived by graphic designers and graphic producers, who combine elements of visual communication (such as images, typography, colors and shapes) with materials and printing processes. These media give way to typologies, which we know and use on a daily basis, such as posters, books, magazines or newspapers, but which had their circulation reduced due to changes of habits and digital transition (Johnson, Goidel & Climek 2014; Rose-Wiles 2013; Twenge, Martin & Spitzberg 2019). This reduction of circulation affects the printing industry and related sectors, such as education or journalism, and disturbs cognition, reading and interpretation, especially of younger generations, for whom screen time affects well-being (Strouse & Ganea 2017; Twenge & Campbell 2018).

Activity sectors focused on printed products, such as the printing industry, the publishing industry or news organizations, have undergone profound changes, which have led to a reduction in revenues and employment (Franklin 2008). Transition to digital alternatives is also affecting education, accentuating unequal access to knowledge and interfering in learning (Mangen, Walgermo & Brønnick 2013; Stoop, Kreutzer & Kircz 2013). Transformation of print artifacts into digital equivalents can be seen as a loss of physical contact (Zhou, Kiesow & Guo 2021), as paper-based material is known to increase comprehension of texts (Delgado et al 2018), and of several advantages associated with these media, such as tactile aspects, linear progression of text, memory cues, annotations and less fatigue (Ackerman & Lauterman 2012; Mizrachi 2014). Print remains an essential part of our culture and society, as a production technology and a means of communication, and its contribute to critical thinking, safeguarding our citizenship and democratic participation seems relevant in a time of information overload.

In demanding user participation scenarios, digitization of products and services has been the prevailing way to deal with print media, although this seems to be a way of accommodating technological innovations that generate doubts about the cognitive, social and cultural capacity of individuals and groups. Media that resort to hyperlinks have been replacing print media, with the digitization of newspapers, books, and magazines, among others, transferred to computers and smartphones (Bødker, 2006). Hyperlinks, which allow dynamic, up-to-date and accessible information, together with the proliferation of the personal computer, the Internet and the consequent technological expansion, led us to believe that print media would become expendable (Nel, 2012). Predominant here was hyperlinking based on the 'point and click' interaction (Moggridge, 2007), which progressed afterwards to include 'drag', 'slide', 'scroll', 'swipe' and other actions that mimic physical manipulations. Then, business cards became profiles on social networks, packaging used RFID technologies and QR codes, and signs became screens. In this context, in which designers were interested in digital representations, the contents of print media transitioned almost directly to digital, maintaining the basic elements of graphic design. When they are not replaced by digital counterparts, print media has provide transition of information, from print to digital, or served as flat surface for overlapped augmented reality (AR) (Gönen & Zeybek 2022; Nadolny 2017; Pellas et al 2019; Sonderegger et al 2019). Still, even such cases do not retain haptic properties of paper and analogue reading and do not integrate interaction as part of the design project. Using print media in interaction scenarios can lead to alternatives to deal with its lack of circulation (Dourish & Mazmanian, 2011). Print media can be contested to not only be limited to transitioning to the digital environment but can also serve as interactive material, enhanced through technological augmentation.

3. Explaining Print Interaction

To help explain ‘print interaction’, i.e., the design of interactive print media, I observed what can be hints of its existence and point out a few notes that can be used to portray it as a new design space, drawing on a relevant number of cases and in research references on related subjects, particularly material or technology-focused.

3.1 Hints

Print interaction acknowledges two parallel or interconnected views: a) print interaction is achieved, within the scope of a circumstantial and limited understanding of interaction, using materials and techniques typical of graphic production, when designed for manipulation and intervention of people; b) print interaction is obtained through the use of materials that resort to printing technologies in some way, connecting in whole or in part to digital systems or artifacts. The latter involves the combination of materials that allow the flow of information and enable interactive printing artifacts to be integrated into digital ecosystems.

a) Interaction through Graphic Production

It may be debatable if print media can be considered interactive without the inclusion of any sort of digital elements, as observed in figure 1. Even detailed accounts that see interaction as a dialogue, transmission, tool, behavior, embodiment, experience or control, are limited to an HCI (Human-computer Interaction) point of view (Hornbæk & Oulasvirta 2017), although interaction can be, most of all, attentive to people's concerns (Bolter and Gromala 2003) and not exclusive of computerized systems (Hallnäs 2004). This would take us on a discussion on interaction as a concept, regardless of technology and focused on its nature and purpose. For a more complete vision and understanding of what print interaction can be, here we can consider as interactive, when it comes to material possibilities that elicit people’s actions and allow anticipated reactions from designed objects (Neves 2012), even if, this takes us to an uncharted context for interaction design. Given its close connection to HCI and computer sciences, interaction design always had stable views on interaction. It emerged as an area to create digital products but has expanded in the meantime, to a spectrum of physical and hybrid accomplishments (Gullick & Coulton 2016; Höök & Löwgren 2021), privileging people's experiences with artifacts and systems. The potential of these designed

objects that use print, together with material opportunities resulted in some experimental technological-driven prototypes that involve print media, or that are related to these media in some way, as seen in figures 2a and 2b. Existing projects point to diversified artifacts, based on technological augmentation of surfaces and information networks. Interaction in print media has found form in works such as *Elektrobiblioteka* (Węgrzyn 2012), *Papertab* (Tarun et al. 2013) or *Interactive Newsprint* (Frohlich et al. 2017).

Figure 1. 'Books with a View' conference poster/book by Marco Neves. This poster contains two perforated lines, so that each person can pull four small parts, join them and fold, thus forming a small book.

Figure 2a and 2b. 'Interactive journey against design fixation' by Mariana Pires. Printed poster with conductive ink, Arduino board and sound column. The poster areas with conductive ink play recorded sounds when activated by touch, which complement the visual experience of the poster.

b) Interaction through Technological Augmentation

Print media are available for transformations and provide an interesting starting point for interaction design initiatives, using various materials or technological resources. In known cases, flexible displays have been used to improve the workspace (Holman et al., 2005); foldable interfaces allow content navigation (Watanabe, Mochizuki & Horry, 2008) and message exchange with material interaction (Khalilbeigi et al., 2012; Tarun et al. al., 2013). E-ink displays together with Arduino microcontrollers experimented in a mobile context (Lahey et al., 2011) and when connected with conductive sensors allow physical manipulation of digital information (Girouard, Tarun & Vertegaal, 2012). Hybrid books (Kelaidis, 2015) with placed sensors and conductive ink, which allows these objects to be input devices, perform tasks and connect with other screen-based devices. Other case presents an augmented experience through a wearable connected to a sensor (Heibeck et al., 2014). These experimental cases advanced in known possibilities for using print media, by adapting materials with technological increment and establishing conditions for interactive resources. They are examples that value such combinations and different uses for known formats, maintaining haptic properties and increasing digital performance. These cases show variables that were not considered in print media until now: i) reaction of the object and the information contained; ii) need for proper affordances to communicate use or interaction; iii) dynamic articulation between parts of the artifact and different human senses; iv) integration of materials that cannot be reproduced on a large scale. Some also resort to paper as a material, which is likely to become interactive through 'technological augmentation' (Margetis, Antona & Stephanidis 2015; Qi & Buechley 2010), with the advantage of providing natural interaction more immediately. Paper is present in various objects with which we already relate, and its interactive inclusion in environments adapted to users is beneficial as it does not become intrusive (Han et al. 2021; Nadolny 2017).

c) Printed Electronics

One of the most immediate aspects is the requirement for material circumstances that allow some form of interaction with media that can be printed. A material and technological possibility that presents a good convergence of this work direction is printed electronics. While some authors have addressed and emphasized the inclusion of new technologies such as AR (Gönen & Zeybek 2022; Nadolny 2017; Sonderegger et. al 2019), or sought to describe the apparent conflict or coexistence between print and digital media (Ballatore & Natale 2015; Nel 2012; Livingstone 2004), printed electronics can allow for planned behaviors between people and artifacts of hybrid manifestation (physical and digital). It is a way to concede interaction to print media, being a technology that involves printing electronic components, such as sensors and circuits, onto flexible substrates, such as paper and plastic (Ramakers, Todi & Luyten 2015). This technology enables the creation of interactive print media by integrating digital elements directly into printed materials (Olberding et al. 2015). For example, printed electronics can be used to create touch-sensitive buttons, sound-emitting components, and light-up displays.

The main features of printed electronics that relate to print media and interaction include: i) flexibility, since printed electronics can be printed on flexible substrates (Khan et al. 2020), allowing them to be incorporated into a wide range of print media, such as posters or packaging; ii) integration, as they can be integrated directly into printed materials or with other electronic substrates (Rivadeneyra, Loghin & Falco 2018), creating seamless and natural interactions between digital and physical elements; iii) low-cost, for they can be produced at a lower cost than traditional electronics, making them more accessible for a wide range of applications (Subramanian et al. 2008); iv) sustainability, as they can be produced using eco-friendly materials and processes (Sudheshwar et al. 2023), making them a sustainable option for interactive print media.

3.2 Contributing Areas

As important as the mentioned materials and technologies can be, in helping explain print interaction, they are not enough to define it as a design space. There are bordering design areas which can contribute to the necessary conceptual framework. These are areas that we can observe in the mentioned cases, but also

and above all, they accumulate knowledge about design and interaction practices, from which lessons can be learned for the future development of print interaction.

Print interaction is based on partial or extensive knowledge and practices from different areas and disciplines, namely interaction design, tangible user interfaces, graphic design and graphic production.

a) Interaction Design and Tangible User Interfaces

Interaction design has been an umbrella designation to encompass different understandings about people's relationship with things, whether specific technologies, systems, artifacts, products or environments. If the recurring vision of a practice centered on the computer and other computerized devices, made common by computer sciences and HCI, prevails as the most considered, it is certain that other positions open the way to contemplate different practices and disciplines (Goodman, Stolterman & Wakkary 2011) or to ease the tension between interaction design and research (Forlizzi, Zimmerman & Evenson 2008). Yet, there is much more that the area has to offer for print interaction, whether in terms of interfaces (graphic, tangible, natural, multimodal) or modality (interaction by touch, gesture, voice).

Research on an interactive perspective of print media so far, has focused on a comparison with most common digital artifacts (Neves 2017). Interaction features were identified in digital artifacts such as operating systems, websites and web-based applications and found their way into printed material. Such physical requirement is consistent with a material turn on interaction (Robles & Wiberg 2010; Wiberg 2018) and can be grounded on the concept of tangible user interfaces (Zheng, Gyory & Do 2020), explained by Fishkin (2004) in three steps: 1) an input event through physical manipulation by hands/gestures on a physical object; 2) a computer system receives such input and changes its state; 3) the system provides an output event, which is the physical change of the object.

Tangible user interfaces, as stand-alone or as shape-changing, meant for individual or collaborative experiences, build on a progressive physical/digital combination, where print media can fit, as other two or three-dimensional products, environments or wearables. Interaction is recognized, perceived and useful in broad, ubiquitous circumstances and without material or technological restrictions.

b) Graphic Design and Graphic Production

More traditional or established areas of design, especially those dedicated to the combination of elements for visual communication, have constituted a solid set of knowledge and modes of action for designers, which are of interest for print interaction.

Graphic design, which is responsible for designing a wide range of materials, including objects produced by printing technologies; editorial design, which has been responsible for the quality of books, newspapers, magazines or catalogues; or visual design and its extensive application in graphic interfaces, on desktop or mobile devices, bring together relevant knowledge for this new space.

The dexterity and organization of media in compositional dynamics, where hierarchy, categorization of information, typographic details, the value and richness of images, the meaning of visual messages, the canvas for exploring semiology, are determining factors to be used for the design of print interaction.

Complementing these visual elements and their communicative ability, in organizing and defining messages, graphic production accumulates procedures arising from various printed reproduction systems, such as the mobile character press, typographic reproduction, lithography, screen printing, offset printing or digital printing. Different printing modes, when combined with different materials (inks, substrates such as paper, post-production materials such as varnishes) and folding, cutting or embossing techniques, contribute to the use of products and the overall experience attributed to them.

The combined management of these elements, techniques and their effects on any experience place them as essential knowledge in the design of interactive print media.

4. Notes for a New Design Space

Based on the mentioned cases, on relevant literature on design and interaction and on material and technological depiction of printed electronics and related possibilities, we can start describing print interaction as a new design-driven space. Print interaction design is a space that combines print media with concepts from interaction design, graphic design and graphic production, enhanced by digital technological augmentation, to create interactive experiences. A few starting notes can help to propel this new design space and clear its future ambitions.

4.1 Tradition

The design of print interaction should consider print media tradition, the long background of visual compositions, and extend its attention to media studies, so it can leverage on media history, consequences, social and cultural interferences as a starting point. Print interaction does not appear from scratch, instead, it owes to common past solutions and tries to improve and update them. A certain emphasis on updating is relevant, particularly in the following aspects:

1. Update print media as cultural and social artifacts with individual and collective significance;
2. Update print media with new or recent materials and technologies that allow data-driven artifacts and inclusion in digital ecosystems;
3. Update print media as design projects, available to be the focus of design processes and methods.

4.2 Cross-Media Design

Print interaction lends itself, out of necessity and out of benefit, to a design-driven approach that emphasizes on cross-media integration, which can be used to create cohesive and consistent experiences across different media channels and for different purposes. Application of printed electronics to print media offers possibilities for creating seamless interactions between digital and physical elements. By incorporating sensors, circuits, and other components directly into printed materials, designers can create interactive print media that responds to users' touch or other inputs, creating immersive experiences. Printed electronics also pave the way for the exposure of print-based messages to the Internet of Things (Janeczek 2020) and consequent information dynamics. Ruotsalainen and Heinonen (2015) already call the internet ‘multimedia’, as it combines the characteristics of different previous media, now articulated. The integration of print media into this constant connectivity is precisely one of the reasons it can be an exciting design space that offers opportunities for creativity, innovation and enhanced experiences. Interactive print media needs to deal with being part of a larger ecosystem of media channels, recognizing the interconnectedness of them all and aiming to develop experiences between them.

4.3 Between Traditional and Emerging Practices

Because it is positioned, even if only in part, as a material achievement and because it is more intended for experiences and relationships with users, than for a unique and restricted physical shape, the design of print interaction appears as an intermediate space, between what are traditional and emerging design practices. Interactive print media fits in a context where several areas of design are dedicated to providing experiences for people, moving away from strictly material needs (Sanders & Stappers 2008). We have witnessed the emergence of 'spaces' in design that seek to address complex (sustainable design, social innovation design) or focused (service design, emotional design) situations, but which separate themselves

from practices now seen as 'traditional' (Sangiorgi 2011) which linked the designer to a know-how and close contact with materials with the purpose of producing something.

Given its observable features, interactive print media aims to reconcile material tradition, especially verifiable in graphic design and graphic arts, in the way information media is dealt with, with the propensity to shape behaviors and consider more holistic experiences, typical of interaction design.

The material tradition to which we allude is not limited only to its tangible side, but rather, it represents diverse contributions to our collective existence, at a cultural, social and educational level.

Instead of limiting itself to being compatible with one side of this comparison, traditional or emerging, print interaction should aim to be a new design space, which, included in a perspective of change, allows:

- the transition from material productions to individual or collective experiences, without giving up physical and tangible contact, but harboring the possibility of dynamic information and adaptation to different situations;
- the possibility of dynamic and updateable information can also avoid a prolonged use of large-scale printing, in the most common model of print media production. This places projects in this design space as contributors to reducing resources and improving the sustainability of the entire process, while simultaneously allowing the renewal of existing products;
- material relationships based on the premise of user participation, transferring control in deciding on the progress or development of products.

4.4 Assessment and Evaluation

Print interaction must focus on testing and evaluating its creations. Concern for people, as well as updating and adapting objects to situations, were largely neglected by print media producers and graphic designers. The necessary investment in reproduction systems forced the maintenance of communication formats. This deprived designers of paying attention to their creations at the moment they were used. An interactive characterization of print media allows for the evaluation of design proposals, particularly in the development phases. This can give rise to better knowledge about usability values, experience metrics, perception of emotions, corrections or adjustments to proposals.

User-centered or human-centered design are key concepts in the development of interactive systems and artifacts. By understanding people's needs and behaviors, designers can create interactive print media that can be intuitive, easy to use, and provide meaningful experiences.

5. Discussion

Like its main contributing areas, a designation and deepening of print interaction is justified, due to the evidence of projects that are characterized in their own way and point us towards a specific direction. Both interaction design and graphic design emerged as terms after one of their practitioners realized the uniqueness of what he was doing. Therefore, this is a first tentative explanation of what can constitute a new design space, because there are observable cases. The majority of these cases can still be referred to as experimental or at prototype level. This fact alone implies the need to collect their findings and aggregate them into contributions and meanings.

Such cases are experimental, and this seems like an admission by those who develop them. The experimentation, at first, seems to be restricted to materials and technologies, although it is not. It appears to be an experimentation with areas of knowledge, with the management of combined elements and with an impact yet to be determined.

The domain of interaction, like design, is expanding. This is positive because we feed practices that can present multiple proposals and that have implications for the socio-economic fabric, but also because we acquire greater knowledge about what we do and what we can do. From here we derive a second reason to recognize this design space, the fact that it can be someone else's scope of action. The need to explain, define and elaborate on print interaction is not only due to what is observable but also as an aid to all those who may want to fit their activity within this framework.

As this is a first attempt at explaining it, the way it is presented may be debatable. Likewise, the initial characterization, included elements, identified areas and mentioned restrictions are debatable. Two of the main starting points that can be questioned are the visual and material overvaluation of print media.

a) Visual Overvaluation

The interpretation followed here is of print media as communication material, whatever its content. This formal levelling may be at odds with positions in media studies or in the printing tradition and the multiple and rich examples it has given rise to. Print media, as assumed here, has been traditionally subjected to design in a visual perspective. Most print materials are thought by ways of visual layout, combining elements such as typography, imagery, colors, shapes and their interpretation of meaning can derive from these elements combined. There are, however, factors that are not considered in this generalization, such as context, culture and geography, which interfere in the production, distribution and perception of meaning and values of print media.

b) Material Overvaluation

Also, as a generalization, all print media is supposed to have material and haptic proprieties, it is distributed and portable through print-sensitive surfaces – from which paper might be the best known and used –, and in some cases are prepared to be handled and allow several gestures. Gesture and handling of print media are fundamental in this appreciation.

Isolating natural gestures that we already have in print media or creating ‘gesture grammars’ close to the physical and recognizable properties in common use, such as in books or magazines, can be an initial advantage. This makes it possible to identify these media as tangible interfaces, a physical material existence to which dynamic graphic information is added. The potential of information flow to be physical and the handling that arises from it places objects that were considered outdated, on the verge of reinvention, transformation, updating, with ramifications for cultural, learning, production and business contexts.

Interactive print-based media proposals present themselves as a manifestation of tangible interaction, expressing limits and understanding of the physical side and its relationship with the transmission of information through digital technologies. These possibilities of physical contact act as motivators for the interactive experience. This description of print media as interactive tangible interfaces can, however, be reductive, immediate and does not ensure, in itself, the correct and complete characterization of the possibilities of physical interaction, for which these media can be made available.

5.1 Tradition vs Future, or How to Begin?

There are two trends, which occur in parallel and which seem to contribute to the explanation of print interaction, or whose influence may be felt in the short term.

The development of systems, services and products, largely based on experiences through screens, sometimes for Web environments, sometimes for physical environments, has been reoriented towards concerns with tangibility, shape-changing interfaces, and interaction beyond human agents, with an attention towards sustainability and a measured use of resources. This development, more comprehensive with social and environmental concerns, with a hybrid propensity, as it occupies places united by the ubiquity of information, has been accompanied by a prevalence of incorporating automatism and 'intelligent' modes in the functioning and use of systems, where interaction emerges as a possible or optimizable way for relationships with people.

Therefore, how does interaction deriving from tangibility intersect with ubiquitous information and intelligent systems, in media arising from or related to print? The temporal connection appears to be difficult. If print interaction needs to respect its tradition, how can we already be looking at future constraints or even risk distorting its benefits due to more technological possibilities? Especially because, in this consideration, the speed of access and use of updatable technological systems can be noted.

Interaction can firstly be introduced in print media by ways of knowledge acquired by designers in dealing with screen layout. Although efforts towards GUI (either on desktop computer operating systems, Web-based applications or smartphone apps), have been to understand them in space and time, designers dealing with print media have tried to mimic them as 2D flat surfaces, ready for visual layouts. So one can expect, as soon as print surfaces become electronic conductors with affordable production systems, designers will try to entangle paper sheets with user interface elements and replicate usability-wise interactions. But from then on, there is already a considerable set of possibilities, to extend the actions of designers, in thinking about printing and its interactive capacity, beyond the two-dimensional.

5.2 A Confusing Technology-Driven Stand

Interactive print media may refer to printed materials that are combined with or incorporate digital elements or a digital connection to create interactive experiences. This print-digital Integration is set to create a seamless user experience, where both print and digital elements can be integrated in a way that may feel natural and intuitive.

Lately, we are able to look at how AR and QR codes are connecting print and digital artifacts and position themselves as ways to contribute to the physical/digital understanding of interaction design. In this sense, print interaction design can focuses on the integration of AR and QR codes with print media. The expected combination creates new possibilities for engagement and interactivity in print materials. By incorporating animations, videos, and infographics, print media may come to life and capture users' attention.

AR is a technology that can be used to enhance print media by overlaying digital content on top of printed materials. Although Yaoyuneyong et al. (2016) present it as more effective than print, AR benefit is to create a sense of immersion and interactivity, making more engaging or memorable experiences that blend digital and physical interactions. By overlaying digital content on top of printed materials, designers can further explore immersive and exciting outcomes. QR codes are a type of barcode that can be scanned using a smartphone camera to access digital content, such as a website or video. QR codes can be incorporated into print media, providing users with easy access to digital content and a simple way to bridge the gap between physical and digital media (Trivedi, Teichert & Hardeck 2020). By incorporating QR codes into printed materials, designers can create experiences that link users to digital content, such as videos, websites, or social media profiles.

Both AR and QR codes can be possibilities related to printed materials. Mainly because they allow movements or additions of information, based on reading or recognizing a printed surface. Still, we can discuss the contribution, enhancement and limitations of AR and QR codes on print media. It may be interesting to clarify what promotes interaction and what enables interaction. AR and QR codes promote interaction, inviting users to use media other than print to shift the focus of action and interact in digital systems. In the case of AR, through a layer of digital information; in the case of the QR code, through the

use of a digital device, which accesses information on a network. However, in both cases, they do not seem to allow print media to be interactive.

When explaining and defining what print interaction is and what makes it possible, we must be particularly attentive to what makes the printed medium interactive and what adds interaction, without necessarily resorting to the printed medium. I argue interaction in print media can have its own combined characteristics given all elements and contributing disciplines and practices. It may be easy to mistake that this initial explanation includes any technological possibility, or that it depends on it. This detail has implications for the design of interactive print media and especially for its future study.

6. Conclusions

An early blueprint is presented to help explain and define print interaction, in what can be a new design space. The main hints and notes were systematized, which could lead us to a definition of a design space for interactive print media. A new design space based on observed design experiments and knowledge collected from crossing areas with a design-led view towards hybrid (physical and digital) interactions, combined with low technology and material resources to maintain the haptic and cognitive benefits of print media.

Print interaction proposes the development of a future vision for objects and techniques that are falling into disuse, based on a dynamic combination, but aware of the material and experimental limitations on which it is based.

Results from this research endeavor will be mainly relevant for interaction designers. Considering print media as interactive provides designers with a new canvas to create engaging experiences, complementing or extending digital services or artifacts. Still, it can also be relevant for research on media studies, graphic design, human-computer interaction and related areas. The great impact can be expected on design projects involving print media and on future research about the materiality of interactive systems. Outcomes will be important to maintain various print media as objects of knowledge communication, for stimulation and preservation of concentration levels when accessing diversified information, to help decrease misinformation and the spread of fake news, for cognitive abilities, especially of younger generations and to help consolidate sectors of economic activity, such as the printing industry.

As it is a first tentative explanation, it paves the way for a set of future research, where several questions may arise. To understand this phenomenon we must then elaborate on:

- how can traditional print media be complemented or reversed through interaction possibilities;
- how can interactive systems, subject to design practice, welcome the presence of print media with interactive capacity in digital ecosystems;
- what are the basic concepts that underpin this design space and how to explain them properly. Above all, those that can be grouped, even initially, from bordering areas, such as graphic design, interaction design, interface design, or user experience;
- how to observe, categorize and study more deeply examples that fit into a design practice where interaction and print media merge;
- how to enable an informed and optimized design practice that contributes to proposals that make the best possible use of this articulation of areas.

To pursue such elaboration, these hints and notes may be of some use.

INSTALLATION "MISUNDERSTANDING OF THE FACADE" — BREAKING AWAY FROM TRADITIONAL VISUAL IMMERSION INSTALLATIONS FOR BODILY IMMERSION.

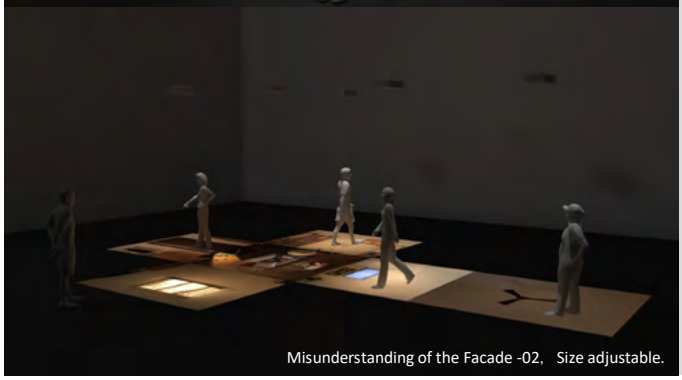
Zixuan Zhou[a], Zhi Wang*[a]

a Canvard College Beijing Technology and Business University, China
* wangzhi@bfa.edu.cn

DOI: 10.63442/XODW1017

KEYWORDS | SPATIALITY, BODILY PERCEPTION, ARCHITECTURE, INSTALLATION, VISUAL CENTRISM

ABSTRACT | Human activity has taken place in a space where the real and the virtual merge, yet our perception of space is still limited by the geometric thinking of traditional architecture. In the real world, space is often viewed simply as the existence of a geometric container, and in the virtual world, space is constructed as a visual spectacle based on XYZ axes. In the media landscape under visual hegemony, the body begins to be absent. We gradually abandon our connection with physical space and turn our perception to the virtual world.

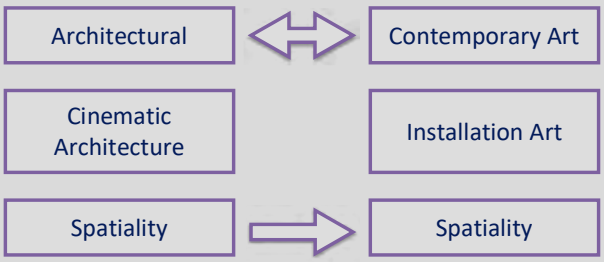


Architectural thinking is reflected in many fields of contemporary art, particularly in its close and profound relationship with installation art. Among these, “Cinematic Architecture” emerges as a new approach in the field of architecture, first proposed by architect Pascal Schöning in the “Manifesto for a Cinematic Architecture” in 2005. Architects no longer perceive architecture solely as physical entities but instead, begin to understand architecture through a cinematic way of thinking. Meanwhile, installation art, as a leading form of contemporary art, utilizes space itself as its material carrier. Therefore, the concept of “Cinematic Architecture” inspires exploration of the potentialities of space in this creative endeavor.

This installation is dedicated to removing the visual centrality and re-conceptualizing the spatiality of everyday architecture from the dimension of the body. It attempts to break the traditional perception of architectural space as a backdrop and create an imaginary space that is constantly reinvented and about memory and emotion. The body is no longer sheltered by the building but becomes an active participant. The term “ facade “ usually refers to the wall of a building. Therefore, the word “Misunderstanding of the facade” is to break the traditional construction of the facade in space, to realise the body’s perceptual wandering through the dissolution of the solid, and to form the individual’s cognition of the space in the path. Through the presentation of the installation, it tries to emphasise the power of bodily immersion rather than visual immersion. No longer creating an object to be viewed, but providing a field, a relationship between the body and space, i.e., space is not a number in numerical measure, nor a form in visual measure, but a perceptual process in bodily measure.

Introduction

Misunderstanding of the Facade -01, 300*250.



Misunderstanding of the Facade -02, Size adjustable.

This installation artwork comprises **two forms**. The first form (01) reconstructs space by presenting partial architectural elements, while the second form (02) reconstructs space by presenting complete architectural facades. Departing from mainstream art gallery formats, such as screen-based exhibitions and white cube spaces, this artwork transforms "form and construction" into "**events and movements**". By manipulating image content and arranging viewing paths, it engages the viewer's body in a roaming, participatory experience, emphasizing bodily immersion over visual immersion.

The term "facade" typically refers to the walls of a building. The artwork removes physical facades and uses images to construct space, resulting in the building appearing fully transparent. Here, the relationship between architecture and people ceases to be shared in physical space and becomes **co-temporal**, thus dispelling misunderstanding of the facade.

Project Focus and Objectives

Conceptual Inspiration

In 2006, architect Pascal Schöning first proposed the concept of "**Cinematic Architecture**" in his article "Manifesto for a Cinematic Architecture," defining it as: "**Space exists through the absence of presence.**"

This aims to understand architecture through a **cinematic way** of thinking.

Text	Objective	Space	Time	Body	Final form
Traditional architecture	The process of constructing entities	Numerical and visual measurements	Linear	Absent, kinematic displacement	A container
Cinematic architecture	The dual process of entity dissolution and reconstruction	Bodily measurements	Fluid and overlapping	Perceptual, participatory	Projection of memory experience

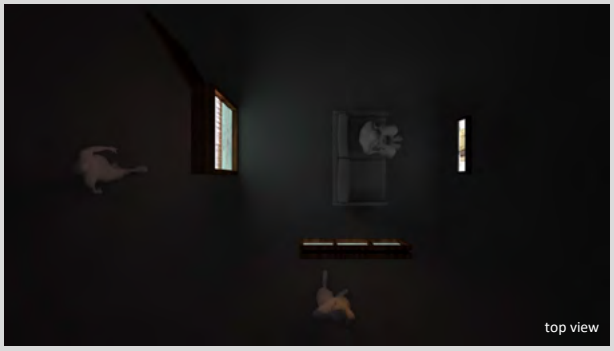
Project Focus and Objectives

Experiential Inspiration

All these imaginations of everyday spaces are based on an incompleteness of space—whether it's a demolished architectural ruin, the beginnings of a construction site, or a glimpse through the doorway of an unfamiliar space. **So, when you construct a complete space, how do you retain this imaginative aspect derived from incompleteness?** This became the starting point of my creative thinking, shaping the design of 01.

Methodology and Tools

Misunderstanding of the Facade -01

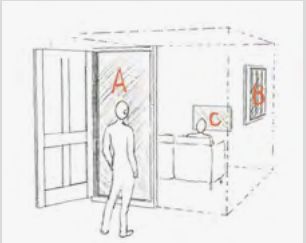


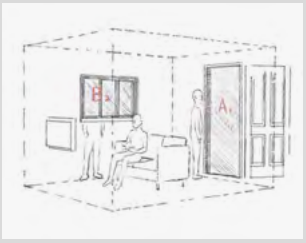
The artwork constructs the entire spatial form through partial images. By combining existing architectural elements like doors and windows with visual content, it approaches tangible spatial places from the dimensions of virtual space. It breaks away from traditional architectural façade thinking, replacing the physical construction of space with the partial representation of space through imagery. Consequently, the spatial form becomes fluid, a result that continuously evolves with the viewer's imagination, achieving visual segmentation and perceptual reconfiguration.

https://youtu.be/LwqvXlX6KVQ

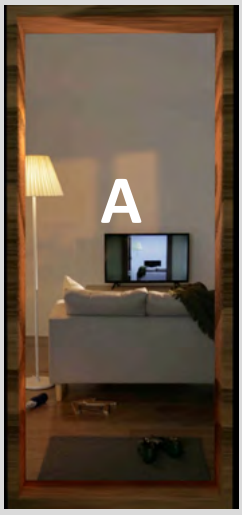
Methodology and Tools

Misunderstanding of the Facade -01





The arrangement of spatial structures on-site guides the movement path of the body, turning the installation space into not just an object of gaze or a mere vessel of service, but a subject to be interpreted and a field supporting dialogue between individuals. As a result, reality and virtuality cease to be attributes firmly attached to specific spaces; they become relative concepts, reliant on real-time frames of reference. The space itself gains existence through human experience.



Creative Process

Misunderstanding of the Facade -01

Spatial Design

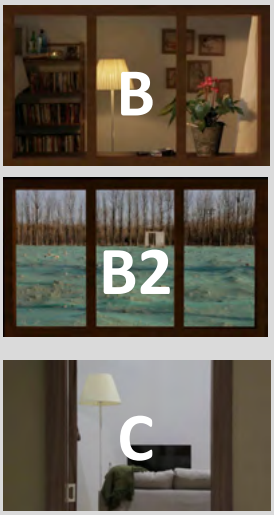


Image Design

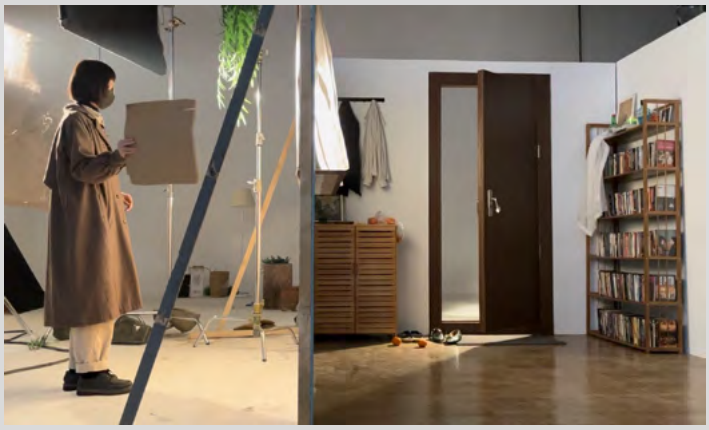
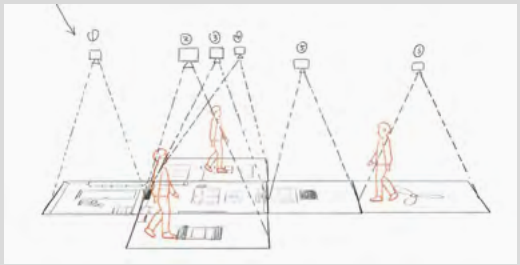
Creative Process

Misunderstanding of the Facade -01



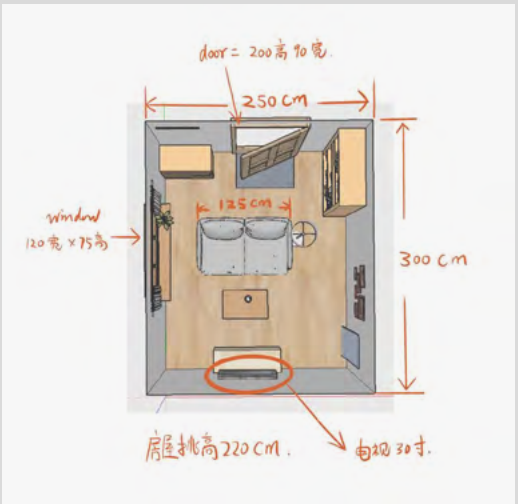
Creative Process

Misunderstanding of the Facade -02



The familiar everyday space being dismantled can evoke a sense of distancing effect, thus giving rise to the second proposal. By breaking the architectural conventions, yet still relying on them to forge new imaginations.

Creative Process



Misunderstanding of the Facade -02

Spatial Design

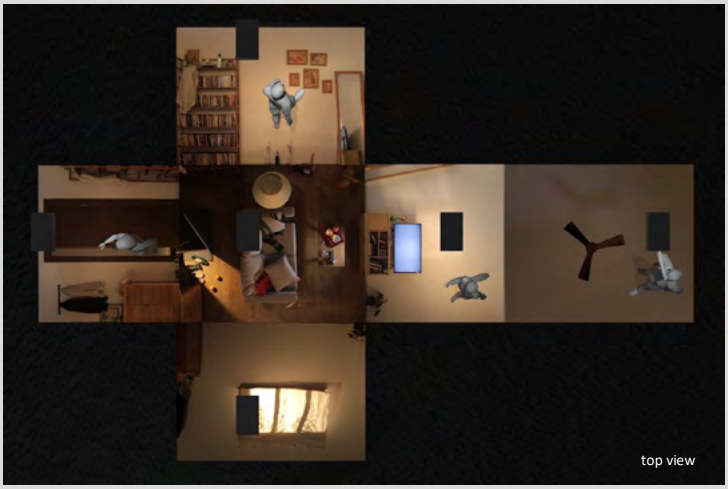


Image Design

Methodology and Tools

Misunderstanding of the Facade -02

This work is based on an architectural stereotype, a residential specification. It disrupts a tangible spatial entity from within, flattening a three-dimensional structure into a two-dimensional plane. The geometric spaces constructed under rationalism are rigorously unfolded through rationalistic methods. The panoramic perspective implies authority and identity. Thus, the viewer's real-life identity and emotions are temporarily replaced by the identities and emotions defined by the visual presentation, allowing a momentary detachment from inherent identities to re-experience everyday architecture.

Methodology and Tools

Misunderstanding of the Facade -02

Completely abandoning the notion of architecture as an enclosure, it allows the viewer's own coordinates to become the sole point of departure. As the viewer enters the projection area, the corresponding images undergo localized changes from a static state. Different facade images are interconnected, and through the collaboration and triggering of various observers, they collectively construct a complete narrative content.

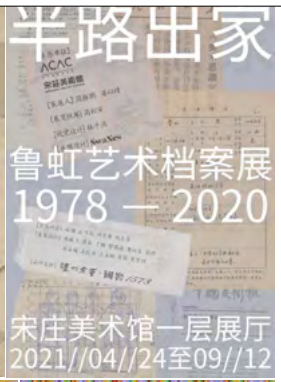
KEYWORDS | DIGITAL HOMOGENIZATION, CONTEMPORARY EXHIBITION, EXHIBITION DESIGN, DESIGN APPROACH, UNCERTAINTY

ABSTRACT | In the rapidly evolving digital landscape, the digitization of exhibitions has led to a pervasive homogenization of diverse displays. Traditional exhibitions, meticulously planned to present information, often prioritize eliminating randomness and uncertainty, resulting in standardized layouts and silk-screen prints. Mechanized and orderly process, while ensuring the seamless execution of events, have unintentionally eliminated the inherent "uncertainty" that exhibitions, as artistic expressions, should embody. This case study involving a Chinese contemporary art critic's archival exhibition adds a practical dimension to the theoretical exploration, reimagines the contemporary exhibition scene by addressing these issues and highlights the pivotal role of uncertainty in fostering diversity and creativity. Examining common forms of expression in contemporary art—namely "writing," "posting," and "found objects"—the paper draws parallels with the exhibition design process. "Writing" and "posting" correspond to printing and hanging, representing subjective and random acts influenced by the curatorial subject, ultimately shaping the final appearance of the exhibit. The use of "found objects" as exhibition props not only saves time and costs but also introduces an element of unpredictability.



Uncertainty, in this context, becomes a catalyst for exploration and experimentation. Designers are encouraged to embrace the unknown, challenging conventional design paradigms, questioning established norms, and cultivating a mindset that values the process as much as the outcome. This departure from cookie-cutter exhibitions allows each design to become a unique journey reflecting the distinct identity of the content it showcases.

By leveraging the inherently random nature of "writing," "posting," and "found objects," this study seeks to turn contingency and uncertainty into the highlights of the exhibition. The intention is to disrupt the monotonous presentation styles of mainstream refined exhibitions and restore the diversity that exhibitions were meant to embody. This paradigm shift aims to redefine contemporary exhibition strategies as a type of contemporary artwork, emphasizing the need to reconsider and redefine the role of uncertainty in curatorial practices. By embracing the unpredictability inherent in these artistic expressions, this paper advocates for a departure from the assembly-line mentality that characterizes many contemporary exhibitions. It encourages a return to the fundamental, diverse, and uncertain nature of artistic expression, urging curators to embrace uncertainty as an integral part of the creative process.

In conclusion, this design research contributes to the discourse on contemporary curatorial practices, highlighting the importance of a more dynamic, inclusive, and unpredictable approach to exhibition curation in the evolving landscape of the art world. It also invites designers and audiences to reconsider the fundamental nature of artistic expression, encouraging a return to the diverse and uncertain roots that define the essence of exhibitions as powerful forms of creative expression in the digital age.

P/REFERENCES OF DESIGN

THE MEANING OF VIRTUAL ARCHITECTURE.

Gabriele Aroni*[a]

a Manchester Metropolitan University, School of Digital Arts, United Kingdom
* g.aroni@mmu.ac.uk

DOI: 10.63442/KIHI1800

KEYWORDS | DIGITAL GAMES, ARCHITECTURE, SEMIOTICS, NARRATIVE, VIRTUAL, VIDEOGAMES

ABSTRACT | Billions of people spend billions of hours in virtual spaces, which are conceived to entertain, move, or even scare. Much of the attention regarding architecture in digital games approaches the topic from a level design perspective, but architectural design can be used in digital games to establish a narration, tell a story, and create specific aesthetic impressions, as well as gameplay situations (Aroni, 2022). Architecture in digital games can also foretell the unfolding of upcoming events rather than simply adding background information on the game setting, a phenomenon that Brian Upton calls "anticipatory play" (2015). This presentation will investigate virtual architecture as it influences and constructs narration – in this context, architecture is understood as the virtual buildings, cities, and interiors present within the games. What are the architectural elements and techniques that create a setting and enhance narration and immersion for players? How do players understand architectural signs?

This presentation will answer these questions by semiotically analyzing virtual architecture as a central signifier in digital games, based on Umberto Eco's architectural semiotic theory, where architectural objects denote a primary function and connote a secondary "certain ideology of the function" (Eco, 1997). The denotative function is the utilitarian function of architectural objects by their forms and material properties. Similarly, virtual architecture has a denotative function as well, related to gameplay. The secondary connotative function of architecture, which can be incidental or absent in real architecture, is even more present in virtual architecture, as every architectural element is deliberately created and placed in the game by the designers. It is the connotative function that communicates to players through architectural signs information about the gameplay, the narrative, and the context of the virtual world.

As space is one of the defining elements of digital games (Aarseth, 2001, p. 154), thus understating how the virtual environment communicates is of paramount importance for the development of effective digital game environments, but also for a deeper understanding of how we perceive the space around us, virtual or otherwise.

AS MUCH AS PAINTING AND OTHER "VIRTUAL" REPRESENTATIONS OF SPACE, DIGITAL GAMES BOTH RECONSTRUCT AND CONSTRUCT EX-NOVO WORLDS, USING SIGNS FROM THE REAL-WORLD ARCHITECTURE AS WELL AS THEIR OWN VOCABULARY.

Cura sui – this phrase pops up today as a recurring name for beauty salons, aesthetic clinics, diet counseling, and the like. Two thousand years ago, however, it was used as a philosophical watchword: 'Take care of yourself' that is take care that your existence, taken in both physical and spiritual sense, is aligned with the cosmos as a whole, with its all-pervading order (since the Greek term of *kósmos* means precisely order), or meet some higher level of (divine) design (Hadot 1995). And it also involved that you ought to take the steps needed to achieve that harmony. Your well-being cannot be conceived as an individual state, only as a partaking in something bigger, an engaging in good in itself.

Well, that is the past of how well-being as an existential state can be apprehended, at least how its understanding went on in the most radical part of its history, in which it has been connected to a philosophical approach and art of living. This attitude has been transmitted through modified forms in the Middle Ages, especially in monastic life: well-being was meant of being close to God. Today, by turn, we are at an interstellar distance from this ancient heritage of the *cura sui,* and much closer to the way of life that Foucault (1986) characterized by the term, "aesthetics of existence". Instead of *cura sui* we have had new and different watchwords for long that have a common feature of each being formulated in a possessive grammatical structure: our Earth, the blue planet; our age, the times of modern life; our design, which is aligned to the human scale.

Our planet – our age – our design: such wonderfully obsolete terms, although still in heavy use! This planet got wounded and is ageing. We, as a society and as individuals, are ageing as well, and disintegrating in many different ways. Our design practices, Papanek warned as early as the 1970s, have proven to be harmful

and dangerous, or ignorant as for planetary and natural conditions (including our very ageing). From this perspective, the last thing we need is even more design. Rather we need care and carefulness.
But can we give and take good care in an all-spontaneous way? Might one conceive carefulness without the implication of prudence, circumspect, foresight, and coordination? Since more often than not there arises a great and multiplied need for care, simultaneously for multiple, both human and other living or nonliving entities, and this leads in itself toward the necessity to assess, organize, and institutionalize what is at stake, the act of design per se, be it product development or policy making, seems inevitable even against their apparent overdriving.

The contributors to this section are testifying their deep understanding and experience of the above tensions. Some of them responded to our call by focusing on specific, intersectional, and institutionally underrated or blindspotted issues: like the situation of the gynecological inspection (V. Juretko), or complex problems of period poverty (Z. de Meillon), HPV detection devices seen from the point of view of the user experience (M. Maldonado et alii). Others approached more directly institutional malfunctions: that of hospitalized children healthcare (C. Akoglu and K. Dankl), burial protocols (M. Kuronen), and urban revitalization (S. Qin et alii). Still others provided examples of careful design in multiple fields highlighting how mindsets are the most important aspects as opposed to technologies (I. Caruso and V. Cristallo; L. Christiansen).

A full panel came together from thought-provoking submissions about how to deal designerly with emerging issues in an ageing society. This was by far the most recurring theme among all the 70+ initial submissions we got on our call, and those that made it until this publication phase are not coincidentally those that put an emphasis on service and technology aspects (A. Giambattista et alii; P. Veske-Lepp et alii; A. Pollini et alii). Their underlying issues are the same as the ones we inherited from the modern design tradition: how can we avoid that our ‘solutions’ lead to ever-increasing alienation?

KEYWORDS | DEATH STUDIES, FUNERALS, ARTS-BASED RESEARCH, SERVICE DESIGN

ABSTRACT | This study investigates the changing landscape of funeral practices, studying the transition from community-involved rituals to professionalized, streamlined funeral processes. Modern funerals have become more privatized, distancing relatives from active involvement and shifting responsibilities to professionals. This shift has led to a lack of personalized rituals and distancing relatives from death, potentially leaving bereaved individuals with unprocessed grief.

Utilizing a service design approach alongside arts-based research methods uncovered nuanced insights into the funeral landscape. This approach facilitated a deeper understanding of the bereaved's needs and shed light on the value of involving slowness in funeral services. Arts-based methods, while emphasizing credibility over conventional validity, provided richer, multidimensional insights into the subject matter. Moreover, reflexive research played an essential role, helping researchers to critically reflect on their assumptions and social constructs.

A key finding of this study lies in the increasing diversity of demands in funeral services and processes, reflecting individualistic desires and varied life-views among the Finnish population. The longing for slowness, a deeper connection with nature, and personalized mourning experiences were the most distinctive themes. Slowness in this context refers not to delaying burial but rather to providing relatives with a considered and deliberate mourning process.

The study's findings highlights the significance of incorporating personalized rituals into the mourning process, challenging the prevalent quest for efficiency and our avoidance of mortality. Slowness in funeral rituals offers a means to confront loss, demystify death, and facilitate healthier grieving processes, ultimately enabling individuals to confront mortality with greater understanding and acceptance.

1. Introduction

In Finland, many people are not familiar with what goes into planning a funeral until they are faced with doing it themselves. Talking about funerals is not common until it becomes necessary, often leading to avoidance until the last minute. As a result, most funeral-related tasks are handled by professionals, leaving grieving relatives feeling sidelined during their loved one's farewell. The post-mortem process has, in various respects, become efficient and effective, yet frequently lacks significance for relatives. However, deliberate and unhurried process is essential to ritualzse, process and comprehend the loss of a loved one. Otherwise, the relatives may feel that they have been left out: *"It felt like a conveyer belt experience, blunt staff who didn't know how to deal with a grieving next-of-kin"* (Participant in web survey, 2017).

The rituals tied to death play a vital role, helping family members cope with their grief and emotions. But these days, funerals are mostly handled by professionals, taking away the family's traditional role. This shift can make relatives feel distant and less involved in the grieving process. Plus, there is still a lot of secrecy and taboo around death in society, even though art and culture often openly explore themes of mortality.

Exploring the issue and taking a developmental approach for the benefit of the family member's experience is important to ensure that everyone has the opportunity to face and deal with the loss. By putting the experience of the relative at the centre and exploring the feelings related to the burial, it is also possible through self-reflection to identify needs and areas for development that cannot be achieved through other methods. Thus, in this study we draw on both service design and arts-based method approaches.

The research questions are:

1. What insights do arts-based research and human-centered design bring to the burial experience? and
2. How can service design contribute to better experiences of loss for the relatives?

Depending on the context, funerals can be understood either as enveloping the entire journey from the moment of death to the burial, or more narrowly as a memorial service. Throughout this article, the term "funeral" refers the entirety of the process.

2. Literature Review

2.1 Finnish Funeral Culture

Finnish funeral culture has become more professionalized over the last 100 years and the involvement of relatives has decreased (Pajari 2014, 64–65; Pentikäinen 1990, 197). Funeral-related services and providers, such as florists, funeral homes, and the church, play a crucial role in facilitating rituals associated with death. Numerous service providers and professionals are indirectly engaged in the process making burial also an economically important factor in Finland.

Rituals aid relatives in confronting their loss and managing their emotions, making them essential for coping with grief. Funerals serve as a means for the community to come together and reorganize following a loss. Often, the rituals surrounding death are influenced by religious practices. (Hakola, Kivistö, & Mäkinen, 2014, pp. 16–17; Pentikäinen, 1990, p. 93). However, the rituals themselves are in the process of changing. For a bereaved, the relevance of rituals to their lifestyle is significant. In contemporary times, internet technology and social media communities provide avenues for individuals experiencing grief to engage in ritualistic mourning and satisfy their need for companionship. (Haverinen, 2014, p. 206).

Art and popular culture frequently draw inspiration from death. However, in our society, aspects such as corpses, mourning, and certain elements of the funeral process are often kept hidden. Unlike birth, which is often openly discussed, death tends to occur behind closed doors metaphorically. Studying this sensitive topic makes death more visible, shedding light on this phenomenon and fostering opportunities for change.

Kimmo Räisänen, a photographer who has captured images of the terminally ill and their families, expressed that "I understand, that it feels horrible that I have taken the photo in this critical hour. However, I think that such pictures must be taken. Death must be made powerless" [authors' translation] (Peltola, 2017). According to Kallinen, Pirskanen, and Rautio (2015, p. 195), research serves as a platform for strengthen the voices of individuals grappling with sensitive topics, providing them with an opportunity to express themselves. By attentively considering these perspectives, it becomes feasible to gain insights on how to develop the funeral services and processes to serve relatives better.

As previously discussed, death often remains a silent and concealed subject within our society, save for its expression in art and cultural mediums like music. Consequently, when individuals are faced with the death of a loved one and require assistance with funeral arrangements, they may find themselves at a loss. In such intimate moments of grief, the significance of rituals becomes heightened as individuals seek guidance from others on appropriate conduct (Poijula, 2002, pp. 92–93). Frequently, the desires of the deceased are ambiguous, necessitating negotiations among relatives regarding the most fitting way to honor their wishes. Molander (2009, p. 40) highlights how death taboos are evident, particularly in the treatment of bodies within hospital settings, where deceased individuals are discreetly transported through back entrances to avoid the gaze of visitors. Nonetheless, there are emerging signs that discussions surrounding death may be gradually shedding their taboo status. Notably, heightened discourse concerning end-of-life care and the legal dimensions of death has drawn increased attention to this significant topic (Ministry of Social Affairs and Health, 2018).

2.2 Service Design as a Human-Centered Approach

The experience of relatives with funeral services and processes can be improved through human-centered methods such as service design. A human-centered approach can be embedded into a design process by examining and considering the viewpoint of the user. Using multiple touchpoints throughout user experiences to create enjoyable and valuable service journeys (Zomerdijk & Voss, 2010; Halvorsrud et al., 2016; Maechler et al., 2016; Miettinen, 2016), service design is a human-centered, multidisciplinary, and transformative design methodology (Sangiorgi et al., 2019; Prestes Joly et al., 2019; Lin et al., 2011). Especially when developing complex services like funerals, it must be understood that the relative is dealing with dozens of different service providers and touchpoints when organizing the affairs of the deceased.

By incorporating people into mapping processes of service user journeys, service design proactively drives value co-creation for continual improvement, an essential component of service design (Yu & Sangiorgi, 2018), for providing services that satisfy functional needs and emotionally connect with users to ensure their satisfaction and the fulfilment of the purpose of the service.

2.3 Arts-Based Research

The arts-based method used was photography, creative notetaking and storytelling. The photos and notes were analyzed by drawing on narrative approaches to visual analysis (Bal, 2001; 2006). In arts-based research (ABR), artistic methods are systematically used as part of the research. Artistic methods can be used in the data collection phase, the operational phase, including analysis, and in the presentation of research results (Barone & Eisner, 2011). The use of artistic methods can achieve the values that designing services commonly require: empathy and change. Empathy makes it easier for us to understand each other's needs and thus enables change. Through art, it is possible to obtain collected material that would not be possible using other methods. Using arts processes in research enables different ways for research

participants and researchers to connect. In addition, the material may be more vivid and nuanced than if the material were collected by other means (Barone & Eisner, 2011, pp. 20–21).

ABR methods focus on credibility rather than validity (Barone & Eisner, 2011, p. 22). Research can potentially gain deeper meanings when utilising other than the so-called clean research methods that supposedly achieve the highest possible validity. However, the use of arts-based methods does not preclude other methods, but the best result is obtained by utilising various ABR methods in the phases of data collection, analysis, interpretation and dissemination of the research (Leavy, 2014, p. 20; 2017). Thus, ABR offers ways for knowing differently as it enables tapping into 'what would otherwise be inaccessible … or out of reach' (Leavy, 2014, p. 21).

Reflexive research (Weber, 2003, p. v) includes the step of taking an intentional break in our activities as researchers for the purpose of reflection, drawing on our ability to reflect on and enhance our understanding by seeing 'the interrelationships among the deep assumptions that underlie our work'. Weber (p. vi) calls on researchers as social beings to 'come to grips with the ways we construct our understanding'. Critical reflection (Fook, 2011, p. 56) can serve as a valuable method in the various stages of reflexive research. The first stage, Fook (2011) suggests, seeks to unearth our fundamental assumptions about social structures and power relationships, to name a few, which enables exploration and enquiry through the recognition of values and beliefs. The second stage draws on new awareness to frame and 'devise new (and better) approaches to practise' that are more suited to our social environments and practices (p. 56).

3. Methods

The research was conducted mostly with qualitative methods: interviews, online survey, photography/visual analysis and creative notetaking as arts-based method, and co-design workshops (Table 1). The studies were conducted between the years 2017 and 2019.

Table 1. DATA COLLECTION METHODS.

Interviews with relatives	n= 13	13 people from all over Finland, aged 34 to 70 years who had organized a funeral sometime in the past
Other informants	n=2	2 persons visiting the cemetery and giving their comments on their visit
Interviews with professionals	n=8	an entrepreneur, a florist, an end-of-life caregiver, a pastor, a senior advisor, an employee of a funeral home, crematorium workers (2)
Co-design with relatives	n=7	1 workshop online, 2 workshops in person
Online survey	n=91	quantitative data with 304 qualitative answers
Observation and self-reflection	n=1	The first author's self-reflection and photos when visiting the crematorium
Creative notetaking	n=5	Creative notetaking with the Mustarinda residency residents
Total of data informants	**n=127**	

The themed interviews were guided by questions, but the focus was placed on the important cues of the participants by encouraging them to continue their stories about their experiences and feelings at the time of dealing with the funeral process. Interviews were carried out with 13 relatives who had organized a funeral sometime in the past. They were from all over Finland, aged 34 to 70 years. In addition 2 informants gave their comments about their visit to the cemetery. It was also vital to understand the service provider's point of view. To accomplish this, an entrepreneur, a florist, an end-of-life caregiver, a pastor, a senior advisor, an employee of a funeral agency and crematorium workers, who also were chapel workers, were interviewed. The objective was to determine what factors affect the experience of those who are arranging funerals from their professional perspective. During the interviews, we discussed the funeral industry and changes in it in general.

The aim of the workshops was to gather ideas from relatives on how to improve burial customs and services. Participants had either organized funerals themselves or had attended a funeral. During the workshops, ideas were collected around four different themes and participants were also given the opportunity to comment on and elaborate on ideas previously collected by other participants. The first workshop was held online and others were held in person. There were in total 7 participants in the workshops.

The web survey's goal was to increase understanding of the funeral industry, generally, and the customer's experiences related to funeral service providers, specifically. There were 92 respondents to the web survey. In every phase, respondents were given the opportunity to respond with an open format reply in addition to a numeric option. This resulted in 304 open replies.

The first author was a resident at artist and researcher residency Mustarinda House in 2019 and collected data during her visit. The thoughts of other residents about funeral rituals and what kinds of rituals they would want to organize for others or would like for themselves were collected by the researcher, supplementing her previous research data. Information was collected from the wall where artists and scholars were encouraged to write and draw pictures of their thoughts. A total of five residents took part in the study. Arts-based methods such as sketching on the walls (Figure 1), instead of only note-taking, were used to collect data, thus supporting different avenues of expression for the participants. Additionally, this approach enabled the participants to process their thoughts differently and enabled us to understand and see differently the assumptions and social structures that underlay the topic of the study.

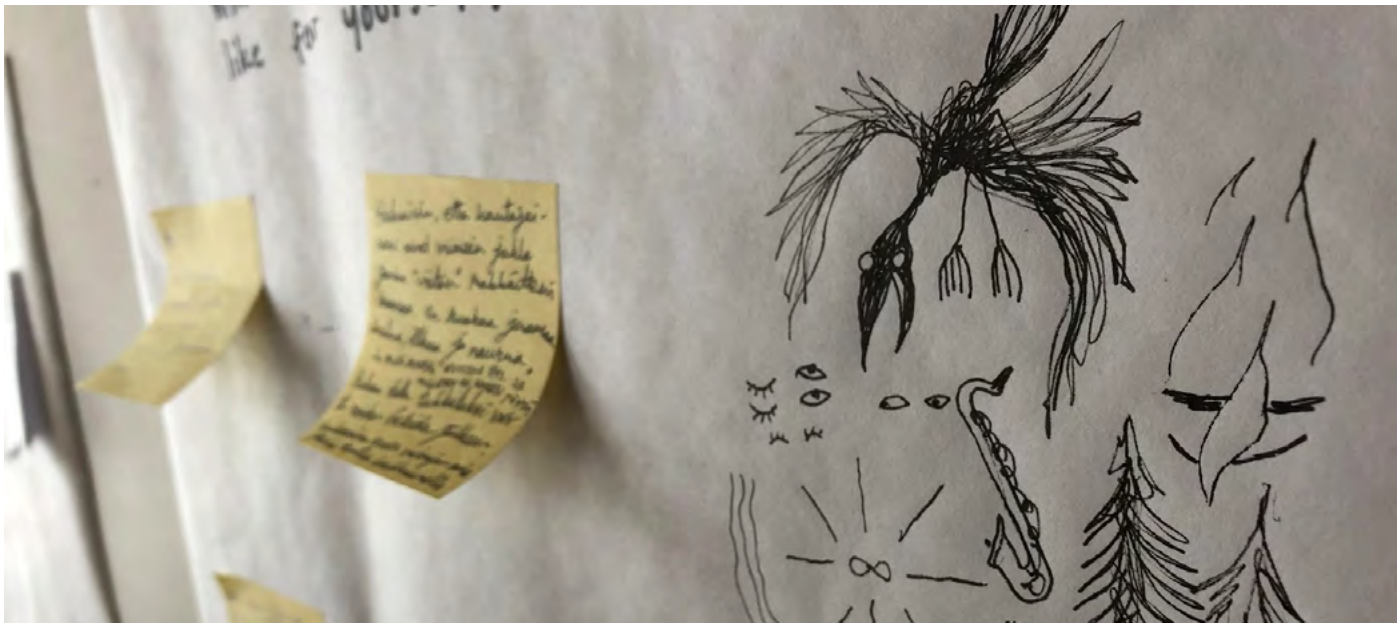

Figure 1. Drawing at Mustarinda House data collection wall.

The analytical approach selected for this study, which was enabled through the reflexive research approaches, was informed by the writings of Bal (2001, 2006) on visual culture and the analysis of visual images as narratives. Bal's approach is based on the logic that visual works contain 'traces' that present clues of how 'the work becomes narrativized' (Bal, 2001, p. 63). These traces are the signs and visual texts in visual images that, once read and interpreted, have the ability to narrate and transfer stories. Such narrativization, once combined with reflexivity, is underpinned by the concept of intertextuality, which 'implies that the adopted sign necessarily comes imbued with meaning' (Bal, 2001, p. 69). Thus, the interpretations coming from the images in this study were 'intertextual' as they transferred meanings across different contexts.

4. Results

4.1 Results of the Data Collecting with Participants

According to the funeral officer we interviewed, fewer people are dealing with death and traditions related to it; for example, fewer are now attending funerals. Obviously, inexperience increases stress and anxiety when the first funeral is to be arranged. In addition to the actual work, funeral officers can potentially play a role in untangling the mysteries and complications that are associated with death. In the interviews with relatives, many stressed the need for slower service experiences and clear instructions as well as a transparent and well communicated process. Funerals are often organized without prior experience, which is why the family members who assume the role of organizers do not always know how to proceed, and they may, and probably do, feel overwhelmed. Funeral officers have recognized this need, and the relatives' role in organizing funerals is usually relatively small. Thus, individualistic choices or one's own rituals are not commonly included. Cultural and religious customs as well as laws also limit self-determined rituals. Relatives often have no information about the deceased's wishes, and this increases the stress. They have a real need for clear, simple and scheduled directions. Practical arrangements such as paperwork should go smoothly for relatives, but dealing with the actual loss often also requires first-hand participation in the burial process. This situation was clearly described by a participant:

> "It would be great if the next of kin had more real-time information about things. As it is, death is hidden behind the funeral home; the idea is that they take care of everything. I think not being able to participate is also stressful for the next of kin." (Participant in web survey, 2017)

In the study, some practiced their own rituals, some in a slightly undisciplined way. For example, one interviewee put keys in a coffin:

> "He lay there quite nicely, the coffin was open and I put the keys of the home in Carelia where he grew up. Even though you're not allowed to put metal inside the coffin, I said 'the hell with it' and did anyway. So it was like he could get home now. He had kept them all his life." (Interviewee, 2018)

Employees of the crematorium also said that they try to fulfil the wishes of relatives as often as possible, not all of which are necessarily in accordance with the instructions. Today, customers desire individualistic choices for funeral artefacts, ceremonies and rituals. Church customs and guidelines, or the views of an individual employee of the church, sometimes limit the options for the rituals of relatives. One of the web survey respondents wrote that they wanted to put a lumberjack's helmet on the coffin at the ceremony, but the pastor had forbidden it.

Some of the participants had also developed their own ways to mourn the loss after the funeral. For example, sisters have a picnic in the cemetery annually and even pour sparkling wine on the grave to the 'delight' of the deceased (Figure 2).

Figure 2. Woman pours sparkling wine on the grave (Picture: Maija-Liisa Kuronen).

Based on the responses from the web survey, it was evident that family members responsible for organizing funerals encountered varying levels of professionalism throughout the service process. Many respondents expressed feelings of stress due to encountering ignorance and unprofessional conduct during the entire journey of organizing the service. For instance, limited resources in terms of space and time in hospitals led to difficulties for relatives and organizers. However, the professionalism displayed by individuals in such situations could significantly impact the experience. An illustrative example of this was an employee who attempted to transform a linen room into a space for relatives to bid farewell to their loved one when no other suitable area was available. Funeral workers emphasized their sensitivity to service experiences and monitored their own behavior to avoid appearing busy. For example, one interviewee mentioned that they never check the time in front of the customer.

The study participants, especially the participants in workshops, expressed a desire for more tangible actions to aid them in coping with their loss, such as shoveling sand onto the coffin, accompanying the ashes, and placing the urn. In many cases the answers reflected the respondents' strong relationship with nature instead of the church. They also explored avenues of self-expression and co-creation, such as utilizing natural stone as a memorial from a meaningful location, planting trees, and crafting coffins. One interviewee even expressed a wish to bake buns and store them in the freezer to be served at their funeral. The data collected through the creative notetaking method also highlighted people's desire for active participation and the importance of nature values. However, the interviewed pastor expressed skepticism towards newer rituals like tree planting, questioning their significance in the absence of established tradition or historical context. They pondered the role of the funeral speaker in such rituals. Nevertheless, they indicated that if such new rituals were not expected to be led by the church, she would not object to relatives partaking in their own farewell ceremonies, emphasizing the importance of allowing individuals to bid farewell in their own way. Interviewed professionals acknowledged the potential for developing new rituals without forsaking established traditions.

4.2 Results of the Self-Reflection and Image Analysis

In this section, the first author of this paper shares reflections from her experience at the crematorium, employing the first-person perspective ('I'). She applied the two steps suggested by Fook (2011) to identify and define the meanings that she saw in the pictures, while also reflecting on, processing and channelling the experiences and thoughts that the participants of the study shared with her.

When I arrived at the crematorium, I was surprised at how harsh, almost cold and extremely simplistic the interior was and the presence of so much concrete. The upper floor was very beautiful, but in an austere way. First, I felt the place was somehow – not sacred – but sensitive, and I was fearing that any misstep, even in the placement of my jacket, could be deemed inappropriate. During the visit, I realized that the crematorium was quite an everyday place. There was no mysticism or spirituality evident, and the cold room was full of human shells, not people. I would not feel comfortable staying alone in the cold room, but I am not afraid of the coffins anymore. I even saw a burning skeleton and felt that the experience made death less awful. The skeleton was no longer complete but a few burning bones. Imaginations of a burning skeleton are much more distressing than witnessing the reality of a burning skeleton in a crematorium.

Burning a body in a crematorium is a very mundane and practical event. Figure 3 shows a coffin ready to be burned in an oven. The coffin is lifted onto the rolling cart. Behind the furnace is a workspace in which the crematory workers supervise the burning of the corpses. The most important thing for workers is to ensure their own safety near the hot ovens and to keep to the schedule given to them. Some relatives ask if they can monitor the burning of the body. The crematorium worker told me that it reduces the mystery of death as the client is introduced to the process without the mysticism, and continued: “And they won’t keep searching for it (the body) anywhere, when they’ve seen it with their own eyes that it’s gone, reduced to dust. It has helped a lot of people”.

Figure 3. Coffin ready to be burnt.

The body disappears into a black hole after one’s life. It even appears like a reverse birth. The atmosphere in the crematorium is unemotional and calm. Steel and tiles give an appearance of efficiency and clinicality. Together with the cart, they form an efficient, clean conveyor belt that efficiently disposes of bodies, the discarded shells of human beings: the viewer may get the impression that it is possible to sweep the dead out of our sight and thus perpetuate the illusion that we have control over our own lives. The coffin is very simple, it is made of unprocessed wood and has cross-shaped screws. The coffin is chosen by relatives and is the only natural object in the picture.

Figure 4. Bones are collected and crushed after cremation.

Figure 4 shows the bones taken out of the oven and three stone balls with which the bones are crushed into ashes. One could easily see something brutal in the picture, but I think crushing the bones is an artisanal stage, even if it is done by machine. At this point, the conveyor belt of the burning of the body seems to slow down, and the crematorium worker picks out foreign objects that are amongst the bones, such as artificial knees and hips made of titanium, porcelain and glass.

Figure 5. A cart in front of a steel desk.

Figure 5 shows a cart that is used to transfer coffins. The cart is empty and is positioned in front of the steel desk that is brightly lit by fluorescent lamps, almost like a spotlight, highlighting the emptiness of the cart. In the middle of the photograph is a black door. This was the first space that I visited when I came to the crematorium. Its coldness felt oppressive at first. Quickly, however, I became accustomed to the facilities, and when I was told that the steel desk was originally meant to be a flower shop I realised my own preconceptions about the premises. Time seems to stand still in the picture. The body no longer exists, but the cart and steel accessories remind us that the body has been eliminated systematically and effectively. Time has stalled, but has the loss been dealt with at the level of mind and body or just swept away? The efficiency of the burial process was also questioned by one of the participants in the web survey (2017):

> "Arranging things went quickly and professionally, but in the middle of grieving, I would have needed a slow service. So I would have had time to think things through."

Figure 6. Room for the farewell to the deceased.

In Figure 6, two metal supports mounted on the wall are depicted, serving as the resting place for the coffin. Additionally, a candlestick holding a lit candle is positioned on the floor, located towards the right side of the image. The room is dim and the walls are made of concrete. The lighting creates patterns on the walls and emphasises its emptiness. There is no coffin, no people and no symbolism related to culture or religion. The word "absence" describes this picture best. It is free from everything; all that remains is a hollow emptiness. However, the areas of light and shadow created by the light bring vibrancy and rhythm to the image.

The images above easily evoke unpleasant emotions, even aversion, in the viewer. This kind of emotion arises from our cultural heritage where anything related to death is both foreign and avoided. We learn in our childhood to fear the things related to death, even cemeteries. Based on these culturally implanted reactions to death, we interpret any images related to it as potentially distressing and intrusive. However, a visit to the crematorium, at the very least, helped me to demystify my thoughts about things related to the deceased. The atmosphere in the crematorium was very different from the image the pictures convey. The employees were nice, and they had highly developed interpersonal skills; after all, they encounter grieving people every day. We drank coffee, and they generously, even proudly, shared information about the important work they were doing.

5. Analysis and Discussion

Death is often unexpected, and relatives need rituals to deal with grief. Many rely on rituals offered by the church because there is nothing else available. However, for processing the loss, it is essential to deal with it through rituals that are personally relevant. The findings from the study indicate that customers will need more opportunities for individualistic choices when organizing funerals and coping with loss.

The first research question asked was, what insights do arts-based research and human-centered design bring to the burial experience. Arts-based research and human-centerd design can be used to identify needs related to burial that support both the smooth running of processes and the emotional experiences of the bereaved. While there is a general desire for services to be efficient, these approaches can be used to identify different needs in relation to burial. Relatives need time and slowness to absorb and understand both the loss they have experienced and the existential, alien, taboo and possibly religious aspects of death. This understanding was gathered in the study, in particular through interviews with relatives and self-reflection and image analysis of the cremation visit. Arts-based research and human-centered design approaches bring out unspoken experiences like preconceptions, the evolution of the bereaved's experience during the process or, for example, the impact of social norms on the relative's experience.

The second research question asked, How can service design contribute to better experiences of loss for the relatives. Service design can improve the carer's experience by putting the bereaved's experience and needs as a starting point, rather than organisational policies and processes. In addition, service design involves understanding the various stages and emotions that relatives go through during the grieving process and customer journey during the entire period. This improves the situation of relatives during a difficult time in their lives. Service design can also be used to identify future needs that service providers can respond to, thus ensuring the future relevance of their services.

According to the current study, relatives need unhurried service when it comes to dealing with a new and unfamiliar matter for them in a situation where they are consumed with grief, not thinking or acting as they normally would. This does not mean procrastination or delaying the burial, but experiencing it without rushing or having time constraints. However, many respondents hoped that the deceased would be buried quickly after their demise because for many the actual mourning began only after the burial. Bereaved needs clear advice, unhurried service, ready-made alternatives and transparency in the burial process.

Involving a relative in various stages of burial, such as preparing the body, make the process more mindfull for the bereaved, and at the same time makes it more humane. If relatives actually take some control of the process of burying their relatives, they can also take the time and actions they need to deal with their loss. The examples in the study showed that, when relatives actively participate in the rituals of death, for example, by being present at the burning of the body, they feel the rituals are more personally meaningful. When one takes the time to fully encounter a loss, for example, by arranging one's own rituals, making something by oneself or even monitoring the burning of the body, it helps to eliminate the mystification associated with death and thus facilitates dealing with the loss. However, it should be noted that each funeral and family experience is unique and the key is to enable everyone to have an experience that suits their needs.

6. Conclusion

The arts-based research used the methods of photography, creative note-taking, and storytelling, enabling slow processes of documentation in reflection by the participants and the researcher. Slowness challenges both our society's quest for maximum efficiency and our delusion that we are immortal. We easily understand our mortality as an abstraction that can be used as an inspiration for art and culture. However, when we have to actually face the death of a loved one, we turn the body over to professionals to take care of and remove it from our sight. Slowness matters when it is time to understand and process the great loss that has taken place.

KEYWORDS | HUMAN-COMPUTER INTERACTION (HCI), SMART TEXTILES, ELDERLY CARE, SOCIAL CARE CHALLENGES

ABSTRACT | In Europe, the ageing population demands innovative solutions to enhance elderly well-being. In the European Union, long-term care services are most often needed by elderly people with health problems. Smart textiles, including electronic textiles (e-textiles), offer holistic care solutions, monitoring vital signs, providing real-time feedback, and supporting cognitive abilities. This paper explores e-textiles' role in addressing elderly care challenges, including physical health, and cognitive performance. The aim is to map the available technology, research, and products already on the market. The challenges, such as privacy concerns, costs, and end-user acceptance, are also discussed. The paper outlines the potential of e-textiles to create innovative solutions for elderly care, and the potential impact of these solutions on society.

1. Introduction

Innovative solutions are increasingly needed to enhance the well-being of elderly populations as communities in Europe age. Elderly people with health problems make up the largest part of those in need of long-term care services (Eurostat, 2020). For example, by 2050, it is predicted that almost 30% of the population in the European Union (EU) will be older than 65 (Eurostat, 2020). In 2020 around 75% of people aged 85 years or more had a long-standing illness or health problem that needed constant monitoring (Eurostat, 2020). More specifically, approximately a quarter of people aged 65 and older in Estonia will be aged 65 by 2030 and 30% by 2060, a significant leap from the 19% recorded in 2016 (Republic of Estonia - Ministry of Social Affairs, 2020). Estonia is a small country with several strong e-services and systems, demonstrating that technology can be seamlessly integrated into daily life. Despite its technology-driven environment, continuous care options supported by technology remain conspicuously absent, yet Estonia's small size can make it an ideal testbed. European care strategy states how the provision of long-term care services (home care, community-based care, and care in residential facilities) should be increased together with adopting quality criteria and standards for long-term care services and supervising their implementation (European Commission, 2022, 2023). In care institutions, elderly care presents a complex landscape of challenges that requires tailored and responsive solutions. Addressing the diverse needs of seniors, electronic textiles (e-textiles) can provide a holistic solution by combining sensory feedback with physical and mental care without losing bodily comfort.

E-textiles are made interactive by incorporating electronics, such as sensors, actuators and soft conductive materials in the textile structure (Hertenberger et al., 2014). Items with e-textiles can provide personalized real-time feedback, for example, support in monitoring vital signs, such as the respiration rate (Guay et al., 2017). Changes in physiological parameters can also be correlated with emotional states. Smart textiles embedded with biometric sensors can measure physiological signals associated with emotions, such as appeasement blanket (SENIORACTU, 2019; STUDIO TWINS PARIS, 2024), heart rate variability (HRV) (Amitrano et al., 2020), skin conductance (Healey, 2011), and temperature (Komolafe et al., 2019) similarly to a smart-watch or a smart ring (Ōura Health Oy, 2024). By detecting changes in residents' emotional states, smart textiles act as empathetic companions. They can improve the mental and emotional well-being of seniors who are isolated or are experiencing cognitive decline. For example, Jiang et al. (2021) developed a smart shawl to visualize physiological data and help regulate emotions. E-textiles can also be highly supportive of communication through tactile and haptic feedback (Schelle et al., 2015). Those solutions can improve the quality of elderly care services, as the care institutions are often short-staffed.

Many e-textile products are available on the market (Levi's et al., 2017; Sensoria, 2022; WearableX, 2022), however, several challenges need addressing to integrate e-textiles into elderly care, particularly in care institutions. To this day, it is customary for innovation and new technologies to reach social care with considerable delay. Many technological solutions that are completely commonplace in the private sector are still little known in the social sector (Republic of Estonia - Ministry of Social Affairs, 2020). The awareness and ability of social workers of different generations to use technical solutions varies greatly, and results in difficulties in introducing innovative solutions in the social sector.

E-textiles offer significant advantages over traditional wearables in healthcare settings, including improved comfort, continuous monitoring, customization, and integration with clothing without limiting movement or adding rigidness, ultimately leading to better patient outcomes and experiences. Thus, this paper explores how e-textiles might be shaping the future of well-being in elderly care, focusing on solutions designed for individual use, and nursing care in hospitals and care institutions. The paper examines the possible role of e-textiles in the well-being and comfort of elderly care in addressing: (1) challenges in physical health together with rehabilitation possibilities; and (2) support of mental and emotional health. The main goal of the work is to analyze current technologies and solutions together with the under-investigated aspects, such as producibility, privacy concerns, high cost, maintenance complexity, and market acceptance. The authors will discuss each of these aspects in the article and demonstrate their importance.

Literature was sourced through Google Scholar (including IEEE Xplore; PubMed; ScienceDirect; ACM Digital Library), Web of Science, and general Google searches (including the European Commission website), encompassing global products. Inclusion criteria emphasized English-language works focusing on technology-supported care, including prototypes, products, services, or studies targeting elderly or long-term care. Exclusions comprised studies not centred on elder well-being or continuous care.

2. Results

This section presents the results driven by the conducted analysis. The authors divided the projects into two umbrella topics: physical and cognitive health support for the elderly with e-textiles.
Figure 1 shows the overview of the division of the result. The physical health topics covered vital signs and movement monitoring, rehabilitation, and safety applications. Providing support for cognitive performance monitoring, assessment, and stimulus as well as emotional well-being was the focus of the cognitive health topics.

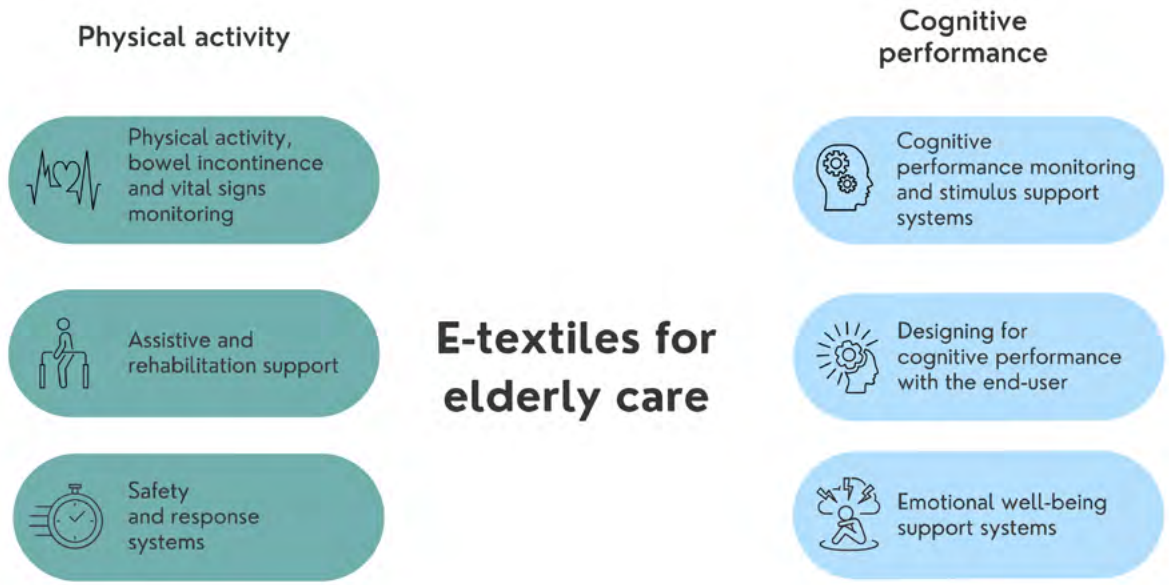

Figure 1. Overview of the results division which consists of two larger topics: Physical activity and Cognitive performance. Physical activity topics are divided into 3 areas: Physical activity, bowel incontinence and vital signs monitoring; Assistive and rehabilitation support; Safety and response systems. Cognitive performance topics are divided into 3 areas: Cognitive performance monitoring and stimulus support systems; Designing for cognitive performance with the end-user (subtopic of previous); Emotional well-being support systems.

1.1 Physical Health with E-Textiles

E-textiles can support comfortable continuous or short-term monitoring of elderly populations with minimal bulkiness and interference with the user's everyday life (Boehm et al., 2016). People's lives can be minimally impacted while supporting healthy ageing and healthcare.

Physical Activity, Bowel Incontinence and Vital Signs Monitoring

Health professionals and caregivers can use movement and vital sign monitoring to assess and manage the health and well-being of their patients. Chronic conditions can be managed more effectively and with lower loss of independence by using continuous vital sign monitoring. Regular monitoring helps healthcare professionals assess the effectiveness of medications and interventions. As a result, individual care plans can be developed more reliably and with fewer resources involved, such as staff involvement, patients' time, etc.

In care institutions, incontinence monitoring is often essential but time-consuming. There are several smart bed systems to monitor incontinence and movement from the bed (Health Quality Ontario, 2018). Fischer et al. (2019) described the development of a sensor mat for detecting urinary incontinence and bed occupancy that can be placed under the bed sheet. Martínez-Estrada et al. (2020), developed a wearable textile system to detect urine leakage. However, these studies were lacking end-user studies, thus, constructive feedback about the comfort and usability of the textile materials.

Electrodermal Activity (EDA) and Galvanic Skin Response (GSR) have emerged as valuable indicators of emotional stress and arousal levels (Healey, 2011; Poh et al., 2010). Electrodermal Activity (EDA) and Galvanic Skin Response (GSR) serve as vital indicators of emotional stress and autonomic nervous system activity, offering insights into overall health and physiological responses. Fluctuations in EDA and GSR patterns may signal changes in sympathetic nervous system activity, potentially indicating pain, discomfort, or medical conditions like urinary incontinence. By integrating these sensors into wearable devices, remote patient monitoring and proactive healthcare management become feasible. Healthcare providers can access collected data remotely, enabling trend tracking, pattern identification, and personalized interventions.

The use of textile electrodes for acquiring biomedical signals to monitor personal and vital functions long-term is one of the most researched e-textile applications (Kubicek et al., 2022). There are several methods of applying, processing and making applications to utilize them. Nigusse et al. (2021) reviewed textile electrodes for the monitoring of ECGs from fundamentals to advancements. In this work, we have emphasized the ones that have been researched for long-term use, more specifically for healthcare and the elderly.

For example, a textronics shirt can show the health status of the monitored person on a mobile device, together with the current date and time of their movements indoors (IPS - Indoor Positioning Systems) and outdoors (GPS - Global Positioning System) (Frydrysiak et al., 2016; Rambausek, 2014). This type of system can support monitoring physical activity and movement in general. However, no end-user tests were described in the reviewed papers. Moreover, using e-textiles with a multi-channel mechanocardiogram (MCG), a wearable system was developed to predict the left ventricular ejection fraction (LVEF) function and provide early warnings about cardiac risk (Lin et al., 2018). Lin et al. (2018) showed an e-textile-based health monitoring system consisting of sensing components, a control platform for the care institution, and a mobile device. The prototype collects electrocardiography signals and monitors heart rates. A fast empirical mode decomposition algorithm was integrated with a hidden Markov model-based algorithm for fall detection for electrocardiography denoising. Wang et al. (2017) and Esfahani (2021) give a comprehensive overview of similar developments and technologies, including body temperature measurements, blood pressure and pulse.

Hexoskin has several products on the market for precise and continuous cardiac, respiratory, and activity monitoring (Hexoskin, 2024). Emglare and Sensoria offer several similar products but only for sports applications (Emglare Inc, 2024; Sensoria, 2022). Sensoria also has Sensoria® Mat to support wheelchair-related in-seat movement and pressure (Sensoria Health, 2024). In general, while the technology seems readily available, it has not reached the elderly care community (Jordan et al., 2023). This lack of access can be attributed to several factors, such as limited financial resources, lack of digital literacy, and lack of government support.

Assistive and Rehabilitation Support

Clothing with embedded electronics can motivate movement and offer location-based real-time simulation feedback for rehabilitation. For example, Vigour “a knitted cardigan with integrated stretch sensors monitors the movements of the upper body to give tailored feedback to the patient’s movement exercises in real-time utilizing sound“ (Ten Bhömer et al., 2013a; Ten Bhömer et al., 2014). Ten Bhömer et al. (2013a) introduced Vibe-ing - a vibration therapy garment that invites the body to feel, move, and heal using electronic circuits in knitted pockets. The prototype with embedded electronics motivated movement and

offered location-based stimulation for rehabilitation. However, no end-user study was introduced. Raad et al. (2019) presented a smart glove for rheumatoid arthritis rehabilitation support. Remotely analyzing a patient's finger flexions while performing various home activities can make an otherwise labour-intensive process more efficient. Yves Béhar's studio, in collaboration with robotics company Superflex, took a step further with The Aura Powered Clothing collection (Morby, 2017). They designed clothes for the ageing population to hold a higher level of physical strength through a series of motors embedded in hexagonal pods. Sensors were placed on the torso, hips, legs, and back. In each "pod," artificial intelligence reacts to the body's natural movements and adds muscle power to help the wearer get up, sit down, or remain upright. The robotics partner Superflex is now a company Seismic which produces similar products but is branded as workwear (Seismic ©, 2022).

Vibroacoustic therapy in e-textiles (blankets, vests etc) can improve well-being and support physical and mental health. In rehabilitation and physical health aspects, vibroacoustic therapy with low-frequency pure sound is found beneficial for muscle tension, chronic pain, insomnia, anxiety and many other mental and physical disorders (Ernst, 2022). However, it is also important to be careful with the vibroacoustic hazards and keep in mind the intensity and frequencies used (Koradecka, 2010).

Phototherapy uses light to treat certain medical conditions. It is most commonly used to treat skin abnormalities, but it can also help with pain management, depression, and anxiety (Seidel et al., 2021). Low-Level Laser Therapy (LLLT) and Ultraviolet light therapy (UV) are commonly used examples of light therapy. Biological response in tissue can be induced by UV therapy by using the electromagnetic wavelength between X-rays and visible light, as opposed to LLLT, which uses a low-powered laser light (Seidel et al., 2021). For example, a conformable blue light therapy device was demonstrated by Jablonski et al. (2014). Shen (2013) and Quandt et al. (2017) demonstrated how luminous polymer optical fibre (POF) fabrics can be used for phototherapy.

Physiotherapy requires a lot of one-on-one time from the therapists. K. Yang et al. (2018) developed a sleeve with electrodes to do seamless muscle stimulation on the upper limb for stroke patients to achieve functional tasks, like hand opening. Liu et al. (2023) described an e-textile-based functional electrical stimulation system for post-stroke upper limb rehabilitation with a small end/user test group. The authors concluded that the fabric electrode offered similar stimulation compared to commercial hydrogel electrodes' performance with the advantage of being suitable for wearable applications and having a long service life.

Moreover, Grimm et al. (2016) described how wearable sensors can benefit the elderly as clinometric tools by counting specific events, such as stairs, or analyzing qualitative parameters, such as step frequency. The article also highlighted that popular consumer activity monitors, such as Fitbit, did not provide the accuracy needed, especially for elderly or disabled patients. Error rates for hip and wrist sensors were more than 60% for both.

Safety and Response Systems

Safety and response systems are essential components of elderly care. However, these systems often lack context-based sensors. Thus, they need activation to work, or have not been developed with user comfort in mind, e.g. materials are not breathable (Medi.ee, 2024; RehabMart.com LLC, 2023, 2024a, 2024b). Movement monitoring technology is evolving rapidly. For example, different IoT (Internet of Things) technologies are available to help monitor remotely and support caregivers - either monitoring the movement with set-up sensors in the room or wearable technology (Ianzito, 2020; Stack Labs, 2023). However, it is still often rejected by the end user due to not trusting the technology or uncomfortable wear (Sung et al., 2022; Tan et al., 2022).

Movement monitoring for safety reasons can have many aspects, like monitoring for wandering or fall (risk) detection. For example, the BalanceBelt is an assistive device that uses haptic feedback to help patients with severe balance disorders overcome their problems and regain their independence (Elitac Wearables,

2024). Using vibrational feedback, the belt detects the direction the wearer is leaning in and alerts them. Moreover, there are several use cases for movement monitoring with e-textiles (Edmison et al., 2004; Elo et al., 2022; Li et al., 2020; Veske et al., 2022). Yu et al. (2020) presented an integrated carpet for self-powered fall detection, using textile-triboelectric nanogenerators (t-TENGs). While the prototype showed excellent first results, there were no end-user tests mentioned.

Furthermore, fall detection is an essential component of elderly care. Similarly to BalanceBelt, (Rahemtulla et al., 2023) investigated near-fall with e-textile socks. The work focused on identifying near-falls, such as tumbles, and more specifically, distinguishing them from falls. USA-based company Palarum offers socks "developed by nurses for nurses to prevent patient falls" (PUP® socks) (Palarum, 2024). Ning et al. (2021) showcased technology for wearable hip-protection airbags to protect the elderly during the fall. One example from the market is TangoBelt (Tango Technologies®, 2022; Tarbert et al., 2021). The belt is equipped with an IMU (inertial measurement unit) that detects falls through an algorithm and deploys an airbag before the user touches the ground. With several examples, Buffagni (2019) gives an extensive overview of this type of research.

Movement monitoring for wandering can be essential in private and care institutions for the elderly due to dementia. While the market offers many remote tracking devices for homes, it can be difficult in care institutions (Just Checking, 2024). Constant supervision requires high staffing numbers. To have quality care with minimal invasion of independence, e-textiles can provide alternative support systems. Fong et al. (2018) proposed how smart clothing can be used in nursing care. The work showed how an emergency can be managed with location tracking by computing the relative position of residents from wireless access points. Sung et al. (2022) made a study with a smart vest that was worn by dementia patients in nursing care. The vest had sensors integrated into them and communicated with movement detectors in the room. However, the authors highlighted that patients were reluctant to wear the vest which is an important note for the product developers.

1.2 Cognitive Performance with E-Textiles

Cognitive assistance technologies, including both textile and non-textile solutions, are being studied alongside passive materials like regular textiles. These innovations aim to offer reminders for medication, appointments, and daily tasks, providing support for seniors facing memory-related challenges (Jiang et al., 2021; Oatley et al., 2021). It is possible to send these reminders through voice, text, or even haptic feedback. As a result, seniors can stay organized and on track with their daily activities, improving their overall quality of life (Motti, 2019).

Cognitive Performance Monitoring and Stimulus Support Systems

Cognitive performance can be assessed and improved through gamification or playful methods. One concept study aimed to both entertain and monitor together with an assessment of the behaviour of people with dementia or its precursor of Mild Cognitive Impairment (MCI) (Oatley et al., 2021). The study used light-emitting diodes (LEDs) and capacitive touch sensors woven into a fabric to augment the traditional activity apron by incorporating light and sound effects as feedback when people interact with different regions of the textile.

Communication can be or feel inhibited by the elderly due to different diseases, loneliness, staying in long-term care institutions or other factors (Comiotto et al., 2016). Vihriälä et al. (2023) highlight the term "complex communication needs". It refers to natural communication methods, such as speech, writing, and gestures, being inadequate to fulfil the person's functional communication needs. Tactile Dialogues are designed to stimulate movement and communication for patients in the late stages of dementia, their family members, and their caregivers (Schelle et al., 2015; Ten Bhömer, 2016, 2022). Through using vibrotactile stimulus patterns and haptic sensations, the developed pillow encourages patients to move and develop conversations in a more alternative yet bodily manner. The project was evaluated in different sessions together with the end-users. Family members were given space and inspiration to encourage their

loved ones with dementia to talk and move more through the prototype. The activity also served as a conversation starter.

A smart shawl developed by Jiang et al. (2021) visualized physiological data and regulates emotions. Based on the wearer's emotional arousal, the prototype captured emotion data using the EDA (electrodermal activity) sensor. Then the emotional state was visualized through light and vibration. Morrison et al. (2018) presented vibrotactile vests that interacted with a vibroacoustic wall in an urban space. This wall was designed to exchange vibrational and physiological information with the wearable vest. In pairs, people interacted with a friend, family member, social friend, romantic partner, or colleague. In two areas of the wall, participants heard and felt their heartbeat and breath rate while performing actions on the wall (such as knocking and swiping). The work reported that in response to the patterns, the participants reported feeling peaceful, therapeutic, and good.

The “Joy, Peace, Grace and Life” project developed a sensory wall (Tan et al., 2022). The polymeric optical fibre fabric was woven with different motifs, and touch-sensitive e-textile embellishments were created using conductive yarn through knitting, embroidery, and other textile constructions. To provide different textures, conductive yarn was combined with textural yarns, feathers, and sequins. Different stakeholders evaluated the prototype: 13 people with early-stage dementia, 9 caregivers, 4 family members, 6 social workers, 1 occupational therapist and the care institution director. Overall, the reception was good, but the authors highlighted that better customization would benefit the prototype.

Designing for Cognitive Performance with the End-User

Literature for elderly care with e-textiles showcased studies that focused on co-designing with caregivers and the elderly. Loss of communication skills can be one of the most significant and detrimental psycho-social characteristics and can have a dehumanizing effect thus creating psychological and emotional distress (Gowans et al., 2007).

Nevay et al. (2015) describe workshops in which older adults living in care institutions designed their own wearables. Design activities focused on craft enabled residents and designers to have new conversations and gain a deeper understanding of residents' real-life experiences, ideas, and skills. Furthermore, Elo et al. (2022) highlighted how diverse studies are focusing on individual applications of assistive e-textiles, few involve a diverse range of stakeholders in the design process. Therefore, the authors organized five multidisciplinary ideation workshops with 50 participants from different backgrounds and roles to gain stakeholder-oriented knowledge on the development of assistive e-textiles. Yang et al. (2022) conducted qualitative research and co-creation workshops to bring together older adults and a multidisciplinary team to develop smart assistive technology solutions. For example, they aimed to identify the critical factors affecting technology acceptability among older adults and how the products should look and feel to be accepted.

Mann et al. (2017) showcased a positive design method involving caregivers in the process of producing customized solutions that are meaningful and helpful. Authors came up with several prototypes, such as a Memory Game to tackle cognitive decline where LEDs were used to interact. Another example is from Jakob et al. (2017), where interdisciplinary research on “Multi-Sensory Environments” for elderly care started by identifying the challenges in the healthcare system and then using a user-centred design approach. The authors also highlighted how textiles have several benefits, such as “creating a warm, comfortable and calm atmosphere reducing negative sensory stimuli such as glares and noise”. Also, members of the general public were invited to participate in Hand i Pocket “funshops” to create sensory textile pockets for those with late-stage dementia (Cardiff Metropolitan University - CARIAD - LAUGH, 2017). The workshops created awareness around dementia and allowed the caregivers and family members to share knowledge and experiences and lose stigma around the topic.

Emotional Well-Being Support Systems

Emotional well-being is essential for any age. However, elderly people can feel loneliness more due to moving to care institutions, lack of everyday contact with loved ones, and other factors. This can cause feelings of isolation and depression, leading to a decrease in quality of life. Different e-textile solutions can support well-being providing comfort, warmth, and a sense of security due to their nice tactile feel.

Treadaway et al. (2015) showcased with several small prototypes that interactive textiles have assisted patients with late-stage dementia in communication and connection with others. Moreover, the results showed they have provided a means of relaxation and distraction and stimulated interest in general (Treadaway & Kenning, 2015). Moreover, Kristin Neidlinger from the Sensoree designed several wearables prototypes to monitor physiological states and translate feelings into auditory, visual, and or tactile displays. Ger Mood Sweater, for example, uses an illuminated collar to read emotion and show excitement levels instantly (Sensoree, 2013). Furthermore, the FleXo prototype acts as a remote physiotherapist by detecting mood and adjusting inflatable acupressure points based on biosensors (Sensoree, 2018).

Multisensory blanket from Maase utilizes non-heat generating LED lights and plush materials to induce a calming effect to aid those dealing with anxiety, autism and sensory processing disorders (SENIORACTU, 2019; STUDIO TWINS PARIS, 2024). The soft glow from the LED lights promotes relaxation, and the plush texture of the blanket provides a soothing tactile experience. Multisensory blankets have the flexibility to integrate various textures and colours, engaging different senses such as touch and sight. This active stimulation can help revive forgotten memories from earlier years by triggering sensory associations and connections. Beyond memory enhancement, these blankets contribute to the overall well-being and safety of elderly individuals. Another study presented a reactive undershirt with embedded textile-based pneumatic actuators that deliver tactile stimulation in response to a change in emotional state to calm anxiety (Goncu-Berk et al., 2020). The prototype has not been validated by end-users yet but such testing is planned (Goncu-Berk et al., 2020; Goncu-Berk et al., 2021).

1.3 Overview

Table 1 shows an overview of tested prototypes and products highlighted in the text. The table overview excluded pure research and proofs-of-concept because they were too far away from the user.

Table 1. Overview of tested prototypes and products highlighted in text.

Category	Sub-category	Solution	Materials	Author	Goal
Physical	Assistive/ Rehabilitation	Vigour	Stretch sensors are made of conductive yarn, electronics, and wool.	(Ten Bhömer et al., 2013b; Ten Bhömer & Van Dongen, 2014)	Measure movement of the arms and lower back, thus, improving the rehabilitation service by keeping the exercises challenging
Physical	Assistive/ Rehabilitation	Smart glove for rheumatoid arthritis	Flex sensor and BLE Nano.	(Raad et al., 2019)	Assist physiotherapists in remotely analysing patients' finger flexions when performing diverse activities at home

Category	Sub-category	Solution	Materials	Author	Goal
Physical	Assistive/ Rehabilitation	Seismic suits	IMUs, sensors, CPU (central processing unit). Materials described: lightweight, breathable	(Seismic ©, 2022)	Reduce muscle strain and fatigue by providing your core with extra power and stability.
Physical	Assistive/ Rehabilitation	Electrode sleeve	IMUs, conductive wires, non/woven fabric with carbon material layers.	(K. Yang et al., 2018)	Training system for stroke rehabilitation
Physical	Physical activity	Balance-Belt	Vibration motors, accelerometer.	(Elitac Wearables, 2024; Kingma et al., 2019)	Correction of body position and improving balance based on haptic feedback.
Physical	Physical activity	MCG shirt	Accelerometers.	(Lin et al., 2018)	Predict the left ventricular ejection fraction (LVEF) function and provide early warnings about cardiac risk
Physical	Physical activity	Hexoskin	ECG & Respiratory sensors and a precise Activity sensor. Textile: 73% Polyamide Micro/27% Elastane.	(Hexoskin, 2024)	Monitoring continuous cardiac, respiratory, and activity
Physical	Physical activity	Sensoria® Mat	Four pressure sensors, Bluetooth-enabled box with electronics.	(Sensoria Health, 2024)	Wheelchair cushion to remind to do pressure relief activities; tracks and monitors the quality of each repetition.
Physical	Safety	Near-fall socks	Microcontroller, IMU, “e-yarns” braided with polyester yarns, knitted sock using Stretchline and Nylon yarns	(Rahemtulla, 2023)	Senses near-fall situations and sends alerts.

Category	Sub-category	Solution	Materials	Author	Goal
Physical	Safety	Palarum - fall prevention socks	Electroconductive fibre with pressure sensors on the bottom	(Palarum, 2024)	Senses fall and send alerts.
Physical	Safety	TangoBelt	IMU, airbags.	(Tango Technologies®, 2022)	Protects the users during a fall by using airbags on hips.
Physical	Safety	Smart vest for dementia patients	Movement sensors.	(Sung et al., 2022)	Tracks movements and sends alerts when needed.
Cognitive	Emotional well-being	Smart sock	Fabric electrodes, electronics.	(Healey, 2011)	Psycho-physiological monitoring system and a wearable sensing unit for emotional reactions
Cognitive	Emotional well-being	Maase	LEDs, speakers.	(STUDIO TWINS PARIS, 2024)	Create a calming effect through music and sound.
Cognitive	Emotional well-being	Different textile artefacts	Electronics, sensors, LEDs.	(Treadaway et al., 2016)	Assisting patients with late-stage dementia in communication and connection with others.
Cognitive	Performance and/or assistance	E-motion-Wear prototype	LEDs, vibration motors, conductive wires, electronics jersey fabric	(Jiang et al., 2021)	Emotional data sensing and visualization through light and vibration.
Cognitive	Performance and/or assistance	Smart textile apron prototype	Electronics, sensors, LEDs.	(Oatley et al., 2021)	Gamification of cognitive tests.
Cognitive	Performance and/or assistance	Tactile Dialogues	Vibration motors, conductive yarn, electronics, cotton.	(Schelle et al., 2015; Ten Bhömer, 2022)	Stimulate movement and communication for patients in the late stages of dementia, their family members, and their caregivers.
Cognitive	Performance and/or assistance	Vibrotactile Wearable Vest and Wall	Vest: 32 vibration actuators, The Zephyr BioHarness 3.	(Morrison et al., 2018)	Wall and vest were to exchange vibrational and physiological information together with people using them.

Category	Sub-category	Solution	Materials	Author	Goal
Cognitive	Performance and/or assistance	Sensory wall	Polymeric optical fibre, conductive yarn.	(Tan et al., 2022)	Support sensory activities to increase social engagement for people with dementia.

3. Discussion

Wearable devices like smartwatches and rings have gained widespread popularity, especially among people keen on monitoring and enhancing their health, sleep, and overall well-being. However, criticisms have been raised regarding their suitability for elderly care, citing issues such as forgetfulness to wear them, discomfort with prolonged use, and difficulty in wearing them (Sung et al., 2022). Despite these drawbacks, they offer durability, reliability, and easy maintenance. On the other hand, e-textile-based clothing shows promise for addressing these concerns, offering comfortable materials and seamless integration of technology. It allows for the collection of movement and other relevant data for personalized care, blending seamlessly into everyday clothing and providing a comfortable touch to the body. However, challenges remain in terms of cleaning and longevity.

This work examined available or researched solutions designed for elderly care for individual use, and nursing care in hospitals and care institutions. The focus was the challenges in physical health together with rehabilitation possibilities and the support of mental and emotional health. The found works are now analyzed based on different aspects, such as end-users (elderly and caregivers) validation, producibility and cost, privacy concerns, materials information, sustainability, and standardization.

However, despite the potential benefits of e-textile-based items, the end-user validations appeared to be lacking. Thus, to make use of the potential benefits of e-textile-based care, there is a critical need for end-user validation and further research and development (Bryson, 2015; Yang et al., 2019). Moreover, research shows that fear of innovation can be a significant barrier to change in social care (Bryson, 2015; Nevay & Lim, 2015; Nevay et al., 2017). Social scientists are essential to such studies and should be part of the future development of e-textile applications for care and their evaluation. Incorporating e-textile technology into care institutions may present integration challenges. Innovative technologies might not always be welcomed, and optimizing the benefits of these tools requires ongoing education. In addition to being comfortable, easy-to-use, and aesthetically pleasing, e-textiles should also support people with varied vision, hearing, physical, and cognitive abilities. Authors believe that as the younger generation enters the field, it may alleviate barriers to integrating new technologies and drive innovation in elderly care. This also prompts reflection on the attractiveness of the caregiving profession, necessitating upgrades to compensation packages and fostering a culture of learning.

Launching new digital solutions can be a significant source of stress for caregivers and other employees, leading to burnout or resistance to work if there is insufficient leadership and support. Thus, caring for caregivers is essential, as evidenced by initiatives like MVO Caring workwear (by-wire.net, 2014), which addresses issues such as posture and air quality to support nurses in their demanding roles. Research by Han et al. (2022) highlights the significant impact of assistive smart textiles in reducing caregiver anxiety, further emphasizing the potential of e-textiles in enhancing the overall well-being of both seniors and those who care for them. To reduce stress during the transition period to technology, the authors emphasize that caregivers must be fully informed of these changes.

The absence of standardized regulations poses challenges in ensuring the quality and safety of e-textiles in elderly care. Social workers, dedicated to the well-being of their clients and communities, may fear unintended consequences or ethical dilemmas that could arise from implementing innovative

technologies. Furthermore, gathering sensitive health data through wearable technology raises privacy and ethical concerns (European Union, 2016a). Authors highlight that striking a balance between safety monitoring and respecting residents' privacy and personal autonomy is essential (European Union, 2016b). Monitoring a vulnerable person requires special attention - if the person can understand their situation, intervention is always based on personal informed consent. Ethical rules are essential and may vary based on the culture, country, and end-user. Furthermore, any type of data collection, analysis and exchange between products is considered confidential data. This can include product sizes, medical data, frequency of use, etc. Additionally, e-textiles require regular maintenance and software upgrades. Ensuring a sustainable, long-term strategy for maintenance and keeping the technology up to date is essential for continued success. They might work better in a service system rather than standalone products. All these aspects were not addressed in the reviewed work and need very strong future developments.

As a result of the regulations and the need for medical documentation, the subject of cost needs to be discussed. E-textile solutions are expensive to implement. Ensuring accessibility for all residents, regardless of financial means, is a challenge that needs to be addressed for widespread adoption. Thus, different smart solutions are often late in the social field and that is caused by several factors (Yang et al., 2019). Social work and related fields are often very distant and unfamiliar to technology developers. Research finds that the market does not seem appealing, because there are often few financial resources and there is no formulated client - often the user and the owner are different (respectively, for example, elderly service user and local municipality). For instance, currently, the social sector and technology-based entrepreneurship in Estonia are still practically separate. Universal terminology, compatible systems, and consensus on data protection and ethical issues are seriously lacking. Any inaccuracies or malfunctions could lead to incorrect health assessments compromise the safety of residents and hinder future technological support system integrations. Materials used must prioritize durability, antibacterial properties, and comfort, including tactile feel and breathability, to maximize user acceptance and adherence. Interestingly, acceptance of such solutions may be higher among individuals accustomed to wearing technology, suggesting the importance of designing for future elderly populations who grew up with digital advancements. Most studies and products in this work did not expand on the textile materials. However, this might be one of the main arguments in user acceptance and, thus, would need to be a part of future developments.

Moreover, our contributions to the world today must meet sustainability regulations and consider beyond human needs to have a positive effect. From the screened literature, only a few highlighted the topic. As an example, Elo et al. (2022) found that sustainability was not a topic raised by different stakeholders in elderly and healthcare workshops. However, Van der Velden et al. (2015) discuss the importance of material selection in developing e-textiles.

4. Conclusions

As the elderly population in Europe is ageing, innovating solutions for care is essential to their well-being, especially for those with long-term health issues. This article provided an overview of how personalized real-time feedback can be provided by e-textiles to address both physical (activity, incontinence, and vital signs monitoring) and mental (cognitive performance and emotional well-being) care needs. This interdisciplinary approach not only benefits the elderly but also shares similarities with designing for individuals with various cognitive abilities (Kuusk et al., 2019) and children (Kubinyi et al., 2021), as demonstrated in educational initiatives. E-textiles promote independence and health in the elderly by utilizing close-to-body technology. Overall, e-textiles can provide feedback to healthcare professionals, allowing them to give continuous support and tailor different rehabilitation programs to each patient's individual needs. This can help to reduce healthcare costs, and accessibility and improve patient outcomes together with early intervention or even prevention.

There are still challenges in using e-textiles in elderly care settings. External factors play a key role – such as the priorities in the society related to a particular problem and the political, economic, and cultural

context. Overcoming these challenges requires addressing issues, such as awareness amongst social workers, producibility, privacy concerns, cost, complexity of maintenance, and end-user acceptance. Despite this, the potential of e-textiles to improve elderly care, particularly when it comes to addressing physical and emotional challenges, demonstrates the need for continued research and development. To have a system that is supported by the social system, these products and practices must be developed closely with the end-users (caregivers and the elderly) to be fully implemented later. Estonia, as a small, technology-driven country can serve as a testbed where e-textiles as part of the care system could be implemented via its lively start-up scene.

About the Authors:

Paula Veske-Lepp (PhD) is a guest professor at the Institute of Engineering and Circular Economy in the TTK University of Applied Sciences. As an engineer, she is interested in designing smart textiles that meet the needs of different end users.

Kristi Kuusk (PhD) is currently a Senior Researcher at the Sensorial Design Group in the Estonian Academy of Arts. She is interested in finding alternative futures for clothing and textile design via the implementation of technology.
www.kristikuusk.com

Helen Kool is a leading lector of social work, with main research interests in elderly wellbeing, social services and technologies in social work and social care. Founder of a Wellbeing Technologies Lab. Has experience in several international projects.

Merje Beilmann's research topics are related to the textile and clothing sector. Her main interest and focus are on the properties of textile materials and product development. She has co-authored several scientific articles.

Ada Traumann's (PhD) main research is in the field of textile technology and the clothing sector. The topic of her doctoral studies was health and safety in the work environment. She has over 20 scientific publications and experience in several international projects.

ABSTRACT | Period poverty is a problem affecting schoolgirls in South Africa and often results in them missing school during menstrual cycles. Concomitantly, discarded clothing is contributing to a growing landfill crisis. To mitigate the effect of these problems, the 'Sustain Her' voluntary community-based project, an initiative by a South African non-profit organisation aimed to utilise discarded clothing to create reusable sanitary pads that could be gifted to schoolgirls. This paper aims to answer the research question: How can clothing waste be utilised to create reusable sanitary pads and empower communities? This aim is pursued by first contextualising the 'Sustain Her' project and secondly by contextualising the opportunities and challenges of the 'Sustain Her' project. The research methodology employed is qualitative autoethnography because the author facilitated and participated in the 'Sustain Her' voluntary community-based project, and the findings of the paper are based on the author's personal experience and observations recorded in personal reflective notes. The 'Sustain Her' project showed that it is possible to recycle discarded clothing to create reusable sanitary pads for schoolgirls, to mitigate period poverty. To that end, community volunteers appeared eager to be involved in the 'Sustain Her' project, and seemed empowered to sort clothing, and perform basic cutting and hand sewing operations. The volunteers' machine sewing skills varied which made achieving a consistent quality of sanitary pad challenging. Several volunteers appeared eager to develop their machine sewing skills but due to various challenges, training was not possible.

1. Introduction

"Period poverty" is a term that refers to the lack of financial means to obtain menstrual products, such as sanitary pads (Department of Women, Youth and Persons with Disabilities, 2019; Michel et al., 2022; United Nations Population Fund (UNFPA), 2022; Vardapetyan, 2021). Period poverty is a global problem that affects millions of women and girls (Michel et al., 2022; The World Bank, 2023). It is estimated that seven million South African schoolgirls suffer from period poverty which results in them missing up to five days of school every month (Ekane, et al., 2014; I_Menstruate, 2023; Kgware, 2016; Khamisa et al., 2022; Modise, 2013). The implication is that period poverty is a potential barrier that may inhibit girls from attaining essential education.

Menstrual products can be disposable or reusable. Disposable menstrual products are only used once for a few hours and are therefore not environmentally sustainable because they result in large amounts of waste (The World Bank, 2023; United Nations (International) Children's (Emergency) Fund (UNICEF), 2019). Disposable menstrual products are often discarded in landfills, flushed down the toilet, which causes sewerage blockages, or burned, resulting in toxic air pollution (Khamisa et al., 2022; UNICEF, 2019). Reusable menstrual products, however, such as sanitary pads made from fabric and silicon menstrual cups, provide a more sustainable alternative because they can be used multiple times and therefore greatly reduce waste (UNFPA, 2022; UNICEF, 2019).

Reusable sanitary pads have the potential to provide a long-term solution to period poverty because they require less financial investment in the long term than disposable menstrual products and can be constructed from fabrics that are easy to obtain, such as from clothing waste. Large volumes of clothing are disposed of annually, with two-thirds discarded within one year of purchase (Dean, 2020; Santi, 2023; Zurich, 2023). Excessive clothing consumption and disposal, coupled with a lack of textile recycling programmes in South Africa, has resulted in an ever-growing landfill crisis (Dean, 2020; Jenkin & Hattingh, 2022; Nkosi, 2022; Qukula, 2022; Rewoven, 2023; Santi, 2023; Wadula, 2022; Zurich, 2023). To mitigate the effect of these problems, discarded clothing could be utilised to create reusable menstrual products and potentially empower communities. This was the goal of the 'Sustain Her' project, an initiative by a South African non-profit organisation (NPO), which aimed to utilise discarded clothing to create reusable sanitary pads that could be gifted to schoolgirls to alleviate the effect of period poverty.

This paper embeds itself in the research question: How can clothing waste be utilised to create reusable sanitary pads and empower communities? To align with the research question, this paper has a two-part aim. Firstly, to contextualise the 'Sustain Her' voluntary community-based project and, secondly, to contextualise the opportunities and challenges of the 'Sustain Her' voluntary community-based project.

2. Literature Review

Menstruation is a normal monthly occurrence for women and girls from the age of puberty to menopause (National Health Service (NHS), 2023; UNICEF, 2018). However, due to lack of accurate menstruation knowledge, the menstrual experience is often accompanied by feelings of shame and secrecy perpetuated by social myths such as ideas that girls are unable to perform everyday activities such as cook food, bathe, or sleep in their own beds during their periods (Barrington et al., 2021; Davis et al., 2018; ElGilany et al., 2005; Hennegan et al., 2021; McMahon et al., 2011; Miiro et al., 2018; Montgomery et al., 2016; Thomson et al., 2019; UNICEF, 2019). As a result of these misconceptions and negative attitudes towards menstruation, and the embarrassment associated with not being able to afford menstrual products, girls are often reluctant to discuss their period-related challenges (Boosey et al., 2014; Dolan et al., 2013; Mason et al., 2013; McMahon et al., 2011; Montgomery et al., 2016; Sommer & Kirk, 2008). As such, despite much research being conducted with regard to the effects of period poverty on schoolgirls, it is possible that the effects of period poverty are worse than currently reflected in the literature. However, the literature suggests that period poverty has a negative effect on the physical, mental, and socio-economic wellbeing of schoolgirls (Department of Women, 2017; Rodriguez, 2021).

Studies indicate that, to overcome the effects of period poverty, some schoolgirls may engage in transactional sex or use inappropriate alternative menstrual products, which can negatively impact their health (Chinyama et al., 2019; I_Menstruate, 2023; Khamisa et al., 2022; Malusu & Zani, 2014; Mason et al., 2013; Montgomery et al., 2016; Nobelius et al., 2010; Ssewanyana & Bitanihirwe, 2019; Tegegne & Sisay, 2014; UNFPA, 2022; Phillips-Howard et al., 2015). Transactional sex in the context of period poverty is the act of trading sexual relations for menstrual products or for money to purchase menstrual products (Tegegne & Sisay, 2014; Tellier & Hyttel, 2018). This behaviour increases the risk of teen pregnancy, early marriage and contracting sexually transmitted diseases such as the Human Immunodeficiency Virus (HIV) (Mason et al., 2013; Tellier & Hyttel, 2018). Despite these risks, studies indicate that sex in exchange for menstrual products is socially acceptable in many countries (Mason et al., 2013; Tegegne & Sisay, 2014).

Alternative menstrual products such as leaves, newspaper, cotton wool and old rags are utilised by many schoolgirls when they cannot obtain menstrual products (Chinyama et al., 2019; I_Menstruate, 2023; Khamisa et al., 2022; Montgomery et al., 2016; Ssewanyana & Bitanihirwe, 2019; Tegegne & Sisay, 2014; UNFPA, 2022). These alternatives are often unhygienic because they disintegrate during use or cannot be thoroughly cleaned, which can cause reproductive tract infections and even infertility (Baker et al., 2017; I_Menstruate, 2023; Mishra, 2015; Montgomery et al., 2012; Ssewanyana & Bitanihirwe, 2019; The World Bank, 2023).

Alternative menstrual products are often ineffective at absorbing menstrual fluid, resulting in leaking and staining on girls' clothing (Chinyama et al., 2019; Montgomery et al., 2016). Studies indicate that visible leaks cause shame and embarrassment for schoolgirls and are often the focus of derogatory comments from classmates (Boosey et al., 2014; Mason et al., 2013; Miiro et al., 2022; Montgomery et al. 2016). Bullying by peers, coupled with the shame of not being able to access menstrual products, causes psychological distress and decreased self-confidence in schoolgirls (Department of Women, 2017; Ssewanyana & Bitanihirwe, 2019; Tegegne & Sisay, 2014).

The fear of embarrassment and bullying increases the likelihood of girls being absent from school during their periods (Boosey et al., 2014; Davis et al., 2018; International Federation of Red Cross and Red Crescent Societies (IFRC), 2013; I_Menstruate, 2023; Mansoori et al., 2020; Mason et al., 2013; Mason et al., 2015; Miiro et al., 2018; Montgomery et al., 2016). Studies further indicate that the fear of menstrual leaking decreases girls' ability to concentrate during lessons and reduces their willingness to participate in classroom activities (Jewitt & Ryley, 2014; Mason et al., 2013; McMahon et al., 2011; Tegegne & Sisay, 2014; Van Biljon & Burger, 2019). Frequent absenteeism and the inability to concentrate in class because of menstrual period associated fears, results in gaps in knowledge, decreases academic performance and increases the likelihood that girls will leave school before completing their education (Boosey et al., 2014; I_Menstruate, 2023; Tamiru, 2014; United Nations Educational, Scientific and Cultural Organization (UNESCO), 2015; UNFPA, 2022). Lack of education diminishes a girl's employment options and increases the probability that she will remain in poverty (Department of Women, 2017; The World Bank, 2023).

In 2017 the Department of Women, a ministry of the South African government, published the Sanitary Dignity Policy Framework (Department of Women, 2017). The aim of this framework was "to promote sanitary dignity" and to set out standards for providing menstrual products to those affected by period poverty (Department of Women, 2017, p. 3). According to this framework, access to menstrual products to ensure dignity during menstruation is a fundamental human right that must be provided for by the government (Department of Women, 2017). Since this framework was published the South African government, in partnership with the private sector, has launched several campaigns to distribute disposable sanitary pads to schoolgirls in low-income areas across South Africa (I_Menstruate, 2023; Parliamentary Monitoring Group, 2018a, 2018b; Van Biljon & Burger, 2019). However, the distribution of these disposable sanitary pads has allegedly been sporadic and unreliable (I_Menstruate, 2023; Parliamentary Monitoring Group, 2018a, 2018b; Van Biljon & Burger, 2019).

Distributing disposable sanitary pads to schoolgirls regularly requires consistent financial investment, which makes this type of campaign challenging (Tegegne & Sisay, 2014), whereas reusable sanitary pads

require a once-off investment because they can be used multiple times, thereby providing a long-term solution to period poverty. Studies indicate that the distribution of reusable menstrual products to schoolgirls, such as silicon menstrual cups and reusable sanitary pads, significantly reduces incidences of school absenteeism amongst girls (Hennegan & Montgomery, 2016; Montgomery et al., 2016; Tegegne & Sisay, 2014; Wilson et al., 2014). As such, it is argued that providing reusable menstrual products to girls affected by period poverty is likely to improve their school attendance and improve their chances of completing their education and escaping poverty.

Menstrual cups are made from medical grade silicon and require specialised knowledge and technology to construct (UNICEF, 2019), whereas reusable sanitary pads are constructed from a combination of absorbent and waterproof fabrics, that are stitched together by hand or with a sewing machine (Tegegne & Sisay, 2014; UNICEF, 2019). This means that reusable sanitary pads can be created by anyone with basic sewing skills and access to the appropriate fabrics. Appropriate fabrics are easy to obtain because large volumes of clothing are disposed of annually (Dean, 2020; Santi, 2023; Zurich, 2023). It is estimated that the rate of fabric and clothing production and the rate at which consumers dispose of their clothing has doubled in the past 20 years (Dean, 2020; Santi, 2023; Zurich, 2023). This is projected to increase in the future, with approximately 148 tonnes of fabric waste being produced by the fashion industry by 2030 (Bailey et al., 2022; Dean, 2020; Stanescu, 2021). It is estimated that at the end of their perceived useful lives, 85% of clothing will be discarded into landfills and 15% will be donated for reuse or recycling (Bailey et al., 2022; Burns, 2019; DeVoy et al., 2021; Ellen MacArthur Foundation (EMF), 2017; United States Environmental Protection Agency (EPA), 2023; Fletcher & Grose, 2012; Kadolph, 2011; Zurich, 2023).

Clothing discarded in landfills decomposes vastly differently (Fletcher, 2000). Natural fabrics such as cotton, silk, wool, and linen decompose relatively quickly, within two weeks to five years (Fletcher & Grose, 2012; Manteco, 2023). This process is, however, retarded by the application of synthetic dyes and chemical finishes during production and if natural fibres have been blended with synthetic fibres (Fletcher, 1997; Manteco, 2023). Synthetic or manmade fabrics such as spandex and polyester decompose over a much longer period, between 20 and 200 years (Fletcher & Grose, 2012; Uren, 2015).[1] As synthetic fabrics decompose, they break down into microplastics and flow out of the landfill in the leachate (Silva et al., 2021; Svedin, 2020; Weinstein, et al., 2016).[2] Despite leachate being treated before it is released into the environment, microplastics are not readily removed during this treatment (Silva et al., 2021; Weinstein et al., 2016). This is problematic because, if consumed, microplastics can cause damage to the cells, inflammation, and oxidative stress (Danopolous et al., 2022; Gerretsen, 2023; Huang et al., 2021). But since synthetic fabrics take a long time to decompose, they contribute to landfills becoming full and being prematurely closed (Fletcher & Grose, 2012; Uren, 2015). This is a problem that South Africa is currently facing. Large metropolitan areas such as Johannesburg and Cape Town are rapidly running out of landfill space (Nkosi, 2022; Qukula, 2022; Wadula, 2022). New landfills could be constructed, but this is a long, expensive process, and requires large areas of land, which is in short supply (Wadula, 2022).

In terms of the 15% of used clothing that is donated for resale or recycling, only 20% is suitable for resale (Schumacher & Forster, 2022). The remaining 80% is donated to the second-hand market in developing countries, recycled into lower-grade fabric goods such as insulation, or discarded into landfills (Schumacher & Forster, 2022). Less than 1% is recycled into new fibres for use in clothing (Schumacher & Forster, 2022). South African statistics are not available, but since fabric recycling programmes are limited in South Africa (Jenkin & Hattingh, 2022; Rewoven, 2023), it is likely that most donated clothing is not fit for resale or donation to the underprivileged and is thus discarded into a landfill.

Creating reusable sanitary pads from clothing waste is not only environmentally sustainable, but it also has the potential to empower communities. The literature documents several programmes in Africa in which schoolgirls and disadvantaged members of the community are taught how to create reusable sanitary pads (Ssewanyana & Bitanihirwe, 2019; Tegegne & Sisay, 2014). These programmes empower schoolgirls to

[1] Synthetic fabrics are derived from petroleum through chemical processing (Kadolph, 2011).
[2] Microplastics are pieces of synthetic fibres that are smaller than five millimetres (Costa et al., 2010; De Falco et al., 2018).

overcome the challenges of period poverty whilst simultaneously equipping community members with skills and knowledge for future employment (Jenkin & Hattingh, 2022; Ssewanyana & Bitanihirwe, 2019).

3. Methodology

The research methodology employed was qualitative autoethnography. Ethnography is the examination and description of social phenomena (Babbie, 2021; Lichtman, 2023; Silverman, 2004). Data is gathered by researchers primarily through observation of the social phenomenon, which is recorded in field notes (Lichtman, 2023; Silverman, 2004). Autoethnography is a class of ethnography in which the researcher records, examines and describes their own experience of a social phenomenon (Çayır, 2020; Poulos, 2021). As such, researchers fulfil the dual role of participant and observer in autoethnographic studies (Çayır, 2020; Poulos, 2021). Autoethnographic methodology was applied in this paper, because the author facilitated and participated in the 'Sustain Her' voluntary community-based project, and the findings are based on the author's personal experience and observations, which were recorded in personal reflective notes.

The 'Sustain Her' project is an initiative of a Johannesburg-based NPO. The project participants included the author, the director of the NPO and community volunteers, including student volunteers from a Johannesburg-based higher education institution. The director of the NPO granted permission for the names of the project and of the NPO to be included in this paper. However, to avoid any possible negative effects because of this paper, and to protect the privacy and integrity of the NPO director, community volunteers, the higher education institution and the schoolgirls who benefitted from this project, all identifying names of people and associated organisations have been omitted.

4. Contextualising the 'Sustain Her' Voluntary Community-Based Project

The 'Sustain Her' voluntary community-based project aimed at creating reusable sanitary pads from clothing waste to reduce waste discarded into landfills. At the same time, gifting these reusable sanitary pads to schoolgirls could potentially reduce the likelihood of absenteeism from school, thereby sustaining their educational journey.

4.1 Clothing Sorting Event

The first phase of the 'Sustain Her' project was to sort through clothing donations and determine what could be used for the reusable sanitary pads. The clothing sorting event was held on Mandela Day, 18 July 2023, at a school in Johannesburg. Volunteers were invited to participate in the clothing waste sorting event via online groups and social media pages. Three types of fabric were required to create the reusable sanitary pads, namely, T-shirting, towelling and waterproof fabric. Volunteers were verbally briefed on the types of clothing to sort. Volunteers were advised not to gather light-coloured T-shirts, such as white or pastel colours, that could be easily stained by menstrual fluid. Once all the T-shirting, towelling and waterproof fabric had been sorted, a large volume of clothing remained. It was then decided by the author and the NPO director that these clothing items could be used to create bags in which to carry the reusable sanitary pads.

4.2 The Development of the Reusable Sanitary Pad

The author developed the reusable sanitary pad design, which consisted of four layers; two outer layers, an absorbent layer, and a waterproof layer. The outside layers were cut from clothing made from cotton T-shirting. The outside T-shirting layers of the reusable sanitary pad were oval shaped for easy sewing, and also provided 'wings' on the sides to wrap around the underwear gusset and were clipped together with snap fasteners. Cotton T-shirting was utilised for the outer layers because of its absorbency, ease of laundering and comfortability.

The absorbent layer was cut from cotton towels and face cloths because the double-knit structure of towelling makes it ideal for absorbing menstrual fluid, laundering and comfortability. The absorbent towelling layer was cut in a rectangular shape, of the same length as the outer layers, and the approximate width of an underwear gusset. This shape ensured that the top and bottom edges of the absorbent towelling layer were attached to the outer layers, with minimal bulk at the width to ensure comfortable fastening around the underwear gusset.

The waterproof layer was cut from faux leather or raincoat fabric in the same oval shape as the outer T-shirting layers. However, few raincoats and faux leather clothing were donated to the NPO, so faux leather fabric was purchased for the reusable sanitary pads to improve their waterproof properties. Pads made with a double layer of raincoat fabric were recommended for light flow days. However, the aim was to make most pads with a faux leather waterproof layer.

The reusable sanitary pad was assembled by first stitching the absorbent towelling rectangle onto the oval waterproof layer. The oval T-shirting layers were then pinned in place on top of the towelling layer and underneath the waterproof layer, and then stitched together. Stitching the edges of the three oval layers together ensured that the waterproof layer could not shift inside the pad during wear or laundering and that the whole pad was waterproof, to prevent leaks. Once the layers had been stitched together, the outer raw edges were overlocked to prevent fraying, provide strength, and promote longevity.[3] Thereafter, snap fasteners were stitched on either side of the oval 'wings' so that the reusable sanitary pad could be secured around the underwear gusset.

Since the outer layers looked the same, a mark was embroidered on the top T-shirting layer, above the absorbent towelling layer. This was done to identify the absorbent side to be placed against the body, and the waterproof side to be placed onto the underwear gusset. To distinguish between the raincoat and faux leather reusable sanitary pads, those with two raincoat layers were embroidered with "L" to indicate use for light flow days, and those with a faux leather layer were embroidered with "H" for heavy flow days.

Schoolgirls were gifted three light flow pads and three heavy flow pads in a fabric carrier bag as part of a reusable menstrual kit. The kit included a small waterproof purse to store soiled pads until laundering. A pamphlet with important menstruation and laundering instructions was also included in the kit, accompanied by soap and vinegar for washing the pads. The components were packed into a small plastic bucket with a lid, to enable discreet washing and storing of reusable sanitary pads.

4.3 Construction Events

The NPO hosted several reusable sanitary pad construction events, during which volunteers cut the fabric layers out of the clothing waste, pinned the layers together, used sewing machines to assemble the reusable sanitary pads and applied hand sewing techniques to embroider 'L' or 'H' on the pads and attach the snap fasteners. Large construction events took place every three months on Saturday mornings at a Johannesburg school. Workstations were set up where cutting, pinning, machine sewing and hand sewing operations were performed by volunteers, in an informal production line. In addition, smaller construction events were hosted on weekday mornings, where unemployed parents and pensioners from the community volunteered to cut out the fabric layers and complete hand sewing operations on already assembled reusable sanitary pads.

In addition to these events, the 'Sustain Her' community-based project partnered with the fashion department at a Johannesburg-based higher education institution to host machine sewing sessions. These sessions took place every Friday morning for a month. In these sessions third-year student volunteers utilised their machine sewing skills and clothing construction experience to assemble the reusable sanitary pads.

[3] Overlocking is a special stitch created with four or five threads which wrap around and enclose the raw edges of fabric to prevent fraying.

As soon as enough reusable sanitary pads had been completed, the NPO hosted a kit packaging event where high school learners volunteered to pack the reusable menstrual kit components into buckets.

5. Findings: Autoethnographic Reflections

At the beginning of this project, the author and the NPO director explored options to create awareness of the aim of the 'Sustain Her' project to provide reusable sanitary pads for schoolgirls. It was determined that the project would be promoted through a poster shared on social media pages, online groups and at community gatherings. The author and NPO director were aware of the culture of secrecy and shame associated with menstruation and grappled with word choice and colour selection for posters, to present the topic of menstruation and the aim of 'Sustain Her' gently to the community. For example, deciding between words such as 'sanitary' versus 'menstrual' and 'towels' versus 'pads' and using pink rather than red in the posters to avoid associations with blood. The project was promoted by the NPO director and community leaders at community gatherings. However, when male community leaders promoted the project, they appeared uncomfortable and often did not share all the necessary information with the community.

Despite this, the 'Sustain Her' project was well supported by the community, with approximately 20 to 30 people at a time attending the various sorting, construction, and packaging events. Most volunteers were women, but there were several young boys and men who participated in the project. Most of the men who participated were fathers of daughters. Over time the culture of secrecy surrounding menstruation appeared to shift in the community as more women and girls began discussing their menstrual difficulties at the 'Sustain Her' construction events. Noticeably more men without children began participating in the construction events and expressed that this was because they wanted to support their female friends who volunteered in the project.

Overall, the sorting, construction and packaging events yielded positive experiences because many volunteers appeared eager to get involved and contribute to the project. It was further observed that bringing a group of volunteers together to work towards a common goal encouraged a jovial atmosphere where people appeared to enjoy the opportunity to meet new people and build relationships in communities. In some cases, such as with adolescents, volunteers seemed to enjoy the social atmosphere to such an extent that the quality and pace of their work decreased, as the construction event progressed. One young man began cutting fabric in the air, because there was no space on the table where he was sitting, as it was surrounded by volunteers. He appeared reluctant to move away from the other volunteers to another available table, despite encouragement from the author and the NPO director.

However, at the sorting events, volunteers initially appeared to struggle to identify and distinguish between the types of fabric. This may be because the author did not show them an example of the reusable sanitary pad that was going to be created, to provide visual context of the fabric required. Additionally, most of these volunteers had not previously made their own clothes, so this may explain their lack of fabric knowledge. To remedy this, the author engaged in a discussion with the volunteers and demonstrated which fabrics and related clothing items were required. Thereafter the volunteers appeared to be better able to identify and sort the clothing correctly.

A few volunteers expressed apprehension because they lacked sewing skills and were not sure how they could contribute to the project. Such volunteers were encouraged and coached to identify and sort the different types of fabric, cut fabric, pin the pieces together, iron the components where necessary and perform basic hand sewing operations. Most volunteers appeared to acquire these skills relatively quickly. However, a large portion of the construction process required machine sewing skills.
A few volunteers, including the higher education fashion students, had extensive machine sewing experience, which was valuable in this project. A notable volunteer was an elderly gentleman in his seventies. His mother had taught him how to sew as a young man and he had been creating and tailoring his own clothing for decades. This gentleman sat for several hours sewing reusable sanitary pads of excellent quality before he asked the author, "What are we making?" The author then explained the goal

of the 'Sustain Her' project to him and he expressed delight at being involved, as he had three adult daughters and seemed to empathise with girls affected by period poverty.

A few volunteers had their own sewing machines, but their experience was limited to making basic clothing items and home soft furnishings such as children's dresses, curtains, and pillowcases. The author assumed that since the reusable sanitary pad consisted of basic shapes, it would be easy for volunteers with limited sewing experience to sew. However, the inexperienced volunteers appeared challenged by having to sew multiple layers of fabric of different thickness and stretch properties together, which resulted in untidy puckering and gathers at the edges. Over time the author found that allocating a few people to pin the pieces together for an inexperienced machine sewer improved the quality of the sewing. This appeared to allow the inexperienced machine sewer to focus on sewing without needing to break concentration to pin pieces together. The author further found that requiring volunteers to pin two layers together with at least ten pins in a radial manner improved the quality of the sewing because the pieces were easier to handle during sewing.

The various levels of sewing experience of the volunteers resulted in large quality variations of the reusable sanitary pads. For this reason, the author checked that all the pads met a minimum quality standard before they were passed on to volunteers for the final hand sewing operations. In some cases, the assembled reusable sanitary pad had a few errors, which required the stitches to be unpicked and the pad to be reassembled. However, in other cases the pads were poorly assembled and could not be repaired and were discarded.

Volunteers attended these construction events when they were able and arrived and left of their own accord. It was therefore not possible to ensure that everyone received the same information and training at the same time. This meant that despite attempts to oversee all sorting, cutting, pinning, machine, and hand sewing operations, volunteers made errors such as cutting T-shirt layers from white fabric, pinning the pieces in the wrong order, not stitching all the layers together, or embroidering the pad on the wrong side. In some cases, these errors could be quickly remedied, but in other cases the errors were only identified when the reusable sanitary pad was almost complete. In these instances, the reusable sanitary pads had to be discarded because they were not fit for purpose. Overall, it appeared as though the sorting, cutting, pinning, machine, and hand sewing skills of the volunteers improved as the project progressed because over time fewer assembled reusable sanitary pads were discarded.

However, a few volunteers, despite coaching from the author, lacked the machine sewing skills necessary to assemble a reusable sanitary pad of sufficient quality that it could be gifted to a schoolgirl. To make the most of their machine sewing skills, these volunteers were redirected to assemble the fabric carrier bags, which were much easier to sew than the reusable sanitary pads. Constructing these bags appeared to be less stressful for the volunteers and they constructed good quality bags at a rapid pace. The construction of bags was led by an older woman in the community who, from the beginning of the project, elected to sew bags rather than reusable sanitary pads. This woman assumed the role of a leader and mentor, by guiding and supporting volunteers in the construction of bags. This enabled the author and NPO director to focus on the sanitary pad construction process.

Several volunteers, particularly school learners, expressed a desire to learn how to use a sewing machine. It was the intention of the author and the NPO director to encourage this desire to acquire new skills and to teach community members to sew. However, time was limited and the primary aim of the 'Sustain Her' community-based project was to create reusable sanitary pads for schoolgirls. For this reason, instead of training volunteers to use sewing machines, such volunteers were trained to identify and sort fabric, cut and pin fabric and perform hand sewing operations.

6. Discussion and Recommendations

The literature suggests that menstruation education for all people plays a vital role in removing shame and secrecy, as well as breaking down myths associated with menstruation (Khamisa et al., 2022; UNICEF, 2019). As such there is potential for the 'Sustain Her' voluntary community-based project to partner with a menstruation education programme as a two-pronged approach to alleviating period poverty in South Africa. Perhaps a representative from a menstruation education programme could accompany the NPO when the reusable sanitary pad kits are delivered to schools.

The 'Sustain Her' project relied on volunteers to create these reusable sanitary pads. As such, the production of reusable sanitary pads can be slow and, ultimately, the schoolgirls are dependent on the volunteers to elevate them out of period poverty. The opportunity exists to teach schoolgirls how to create their own reusable sanitary pads so that they are empowered to elevate themselves out of period poverty. However, this would require the provision of the fabric and sewing equipment, in addition to providing schoolgirls with sewing lessons. This requires a greater resource investment than is currently available. The author is exploring possibilities of creating reusable sanitary pads that can be constructed exclusively through hand sewing operations from clothing waste, to overcome the challenges of providing sewing machines to schoolgirls.

The literature indicates that several reusable sanitary pad programmes employ community members and train them to create reusable menstrual products (Jenkin & Hattingh, 2022; Ssewanyana & Bitanihirwe, 2019). The possibility therefore exists that the skills acquired by volunteers during their participation in the 'Sustain Her' project will enable them to gain employment in clothing production or to start their own businesses creating reusable sanitary pads.

The author and the NPO are further exploring the possibility of creating a social media instructional video to provide step-by-step instructions on how to construct a reusable sanitary pad from clothing waste. This endeavour may inspire people who possess machine sewing skills to initiate similar projects to reduce the effects of period poverty in their communities.

However, it is noted that schoolgirls affected by period poverty likely also lack underwear. Lack of underwear makes the use of reusable sanitary pads difficult. As such the author and the NPO director are exploring campaigns that can be initiated to obtain funds to purchase underwear so that a pack of underwear can be included in each reusable sanitary pad kit.

The potential further exists for researchers to explore and quantify the amount of clothing that is diverted from landfill through the creation of reusable sanitary pads, as well as to examine the long-term effects of the 'Sustain Her' community-based project on breaking down menstruation myths and alleviating the effects of period poverty on school absenteeism.

7. Conclusion

Period poverty is a global problem affecting millions of schoolgirls. Not only is period poverty a barrier to accessing education, but it also has a negative impact on the physical and emotional well-being of schoolgirls. Provision of disposable menstrual products by state and privately funded campaigns is often sporadic and unreliable. Additionally, disposable menstrual products produce large amounts of waste, which is environmentally unsustainable. Reusable sanitary pads made from clothing waste are a potential long-term solution that overcomes the challenges of period poverty faced by schoolgirls and simultaneously prevents clothing waste from being discarded. As such, reusable sanitary pads made from clothing waste are a sustainable alternative to disposable menstrual products.

This paper set out to answer the research question: How can clothing waste be utilised to create reusable sanitary pads and empower communities? This was pursued by contextualising the 'Sustain Her' voluntary community-based project, as well as contextualising the opportunities and challenges encountered during the 'Sustain Her' project. The 'Sustain Her' project showed that it is possible that the design and making of sustainable solutions can be used as a strategy to recycle clothing that would otherwise be discarded into landfills, whilst at the same time empowering communities to develop new skills and potentially support the wellbeing of schoolgirls affected by period poverty.

Figure 1. Reusable menstrual kit including a bucket, instruction pamphlet, bottle of vinegar, soap and soap dish, waterproof purse, six reusable sanitary pads and a fabric carrier bag (underneath the reusable sanitary pads).

ABSTRACT | Social designers' involvement in healthcare and well-being has been steadily growing. Their roles have expanded to encompass various facets well beyond products and services towards seeking to make an impact on a holistic level aiming to enhance the overall patient experience. However, there is a lack of research into overarching objectives and qualities that social design can add to healthcare. As a response to this gap, the study aims to delve into and explore potential areas where social design can make contributions within healthcare for/with children. As a response to this gap, this study explores three case studies from a master's programme focusing on social design and participatory design in Denmark. The three case studies cover various aspects of healthcare involving the creation of environments and experiences that promote healing, comfort, and a sense of safety for patients. The analysis of these three case studies point out to four qualities that were added by social design: encouraging patients' and parents' agency, increasing engagement, fostering a sense of wellbeing and enhancing patient satisfaction. These provide insights that can guide future initiatives, strategies, and collaborations aimed at integrating social design principles to enhance healthcare delivery and improve outcomes for patients and communities. This paper suggests that a social design-led approach to healthcare for children working closely and continuously with patients throughout the project, could assist in creating value-driven services and thus increase the overall quality of care.

1. Introduction

This paper's overall perspective is social design which inherently bases its work on participatory and co-design methods to ensure a people-centric approach throughout a project.

Social design contributes to the concepts that inform the creation and organization of social systems, structures, and interactions to achieve positive outcomes for individuals and communities (Armstrong et al, 2014). These concepts are often applied in fields such as urban planning, technology design, community development, organizational management, health, and social care. While specific points may vary depending on the context, social design consists of the following fundamental aspects: a) inclusivity and diversity, b) participation and co-creation, c) empathy and equity, d) accessibility, e) resilience f) cultural sensitivity, g) continuous feedback and iteration, g) transparency and accountability (Nold et al.,2022). Markussen (2017) argues that social design is created out of a collaborative design process where designers involve a specific group of citizens, public and private partners to achieve social change, with the aim to improve life conditions for a disadvantaged and confined social group or community. Markussen sees micro-scale effects that may reach a meso-level, but stresses that these effects rarely break out of their limited frame, meaning that the social value is conceived of as a small, but decisive qualitative change in the form of a re-distribution of identities or interpersonal relations. (Markussen, 2017:169).

Studies show an increasing focus on children's psychosocial well-being in healthcare environments (Lambert et al., 2013; Bishop, 2014), in healthcare technology design (Iversen and Brodersen, 2007; Sims 2018), and in healthcare services (Miettinen and Alhonsuo, 2019; Russell et al., 2014). This increasing focus resonates with social design referring to the intentional and collaborative process of creating, shaping, or improving healthcare services, products, and spaces with a primary focus on enhancing the well-being and experiences of individuals and communities within the broader social context. Focusing on patients - in this scope, children's - experiences in the design of healthcare services, products, and spaces is of paramount importance for several compelling reasons. This does not only enhance the quality of care but also contributes to improved health outcomes, increased patient satisfaction, and gradually a more efficient and effective healthcare system (Harris et al., 2015).

This paper aims at bringing up what future social designers should be cautious about when designing healthcare with/for children as well as showing and discussing why social design is especially suited to contribute to the healthcare design with/for children.

Unlike traditional design approaches that may prioritize aesthetics and functionality, social design in healthcare places a strong emphasis on understanding and addressing the social, cultural, economic, and emotional aspects of patients' lives as well as the aesthetics and functionality. In this domain, social design emphasizes a people-centric approach, fostering collaboration, empathy, and inclusivity to create services, products, and spaces that contribute to the overall patient experience by following an empathic, co-creative, inclusive approach with continuous feedback and iteration. However, there is a lack of research into overarching objectives and qualities that social design can add to healthcare. As a response to this gap, this study aims to delve into and explore potential areas where social design can make contributions within healthcare by presenting three case studies from a master's programme focusing on social design and co-design in Denmark. The three case studies cover various aspects of healthcare involving the creation of environments and experiences that promote calmness, comfort, and a sense of safety for patients.

Existing research in healthcare with a focus on children reveals three main areas that are covered: (1) healthcare technology design with children and its respective methods, (2) interior design of hospitals with an eye on children's needs and (3) the service design of healthcare and children's needs.

In the following sections, first, a portrait of existing relevant research is presented; this is followed by elaborating on the three case studies via going deeper into the approaches taken and methods used. With

these in mind, a set of values that social design practice brings into the domain of healthcare are proposed towards the end of the paper.

2. Healthcare Technology Design with Children and its Respective Methods

Traditionally technology design with children focused on human–computer interaction (HCI), emphasizing on acquiring information from mediators such as teachers and parents, with scarce involvement of children themselves (Druin 2002). It seems to be common ground that working with children in a technology design process is more challenging than working with adults for several reasons: Hanna et al (1999) argue that children have more difficulty in vocalizing their thoughts, so techniques such as thinking aloud tend to be more challenging to use. The interval during which children can concentrate, as on a single object, idea, or activity is more limited (Markopoulos and Bekker 2003). And finally, methods need to address and acknowledge the power relation between children and adults (Punch 2002).

However, suggestions and frameworks for children's involvement that address these challenges have been made (Druin 1999; Harvard and Løvind 2002; Isomursu et al.2004). These focus on analysing children's joint interactions with a particular design proposal- ideally with a 'fun' factor - rather than focusing on solicitating direct feedback. Methods like peer tutoring following these suggestions: children form a peer group for testing and rehearsing a design. A researcher introduces the first child to the design solution and shows the child how to use it. After a few minutes of practice, the child becomes a tutor to the second child; again after 15 minutes the second child, the tutee, becomes a tutor to a third child and so forth. Observations of the interaction between design proposal and children's up-take of it can be used for design iterations (Druin 2002). The BRIDGE method, developed by Iversen and Brodersen, stresses that it is the designer's and design researcher's duty to enable equal contribution to design from children and adults by adapting language, materials and environment accordingly rather than focussing on children being considered as cognitively incomplete (Iversen and Brodersen, 2007).

Those projects that do engage in healthcare technology design typically include informal and formal user-centred design methods. As an example, Weightman et al (2010) worked with children with cerebral palsy to design engaging, playful hardware and software devices for upper limb rehabilitation. The methods they used in their iterative design include questionnaires, interviews, peer tutoring inspired by Druin (2002) and a comparative method. Studies highlighting methods available for children with special needs include Allsop et al (2010). They analyse available methods such as co-inquiry, cooperative evaluation or the above-described peer tutoring and their potential barriers for children with special needs and call for an inclusive adoption of methods to give a voice to these children. Sims (2018) involved kids in co-designing children's upper limb prostheses by applying the conversational BRIDGE method (see above). The researcher also stresses children's "opportunities to develop social, academic and design skills and to develop autonomy, which can be further enhanced by ensuring children are afforded equal rights as adults when deciding whether to participate in research." (Sims, 2018:25).

Thabrew et al (2018) offer an interesting review of eHealth interventions that were developed via co-design with children and young people. A computer game for treating anxiety in children with long-term physical conditions, a self-monitoring app for use during treatment of depression in young people, and HABITS, the development of an emotional health and substance use app, and eHealth platform for young people, are used to discuss the value and challenges of co-design processes. (see Thabrew et al, 2018:1) Projects used probing, toolkits and workshops adapted to their specific contexts and authors concluded: "Co-design can successfully be undertaken with children and young people. However, additional thought needs to be given to settings and techniques to ensure meaningful engagement and participation from these groups." (Thabrew et al, 2018:5).

3. Interior Design of Hospitals with an Eye on Children's Needs

Hospitals are usually seen as environments that provoke the feeling of fear, sadness, anger, anxiety, loneliness, and homesickness for children; studies show that all these emotions have an impact on children's physical and psychosocial well-being (Lambert et al., 2013; Bishop, 2014) while some additionally point out to how those also impact parents' stress levels (Cartland et al., 2018). To overcome these emotions and create child-friendly healthcare environments, literature emphasizes the importance of involving children directly or children's parents in the design and development of such spaces (Coad and Coad, 2008; Lambert et al., 2013). Among those, Li et al (2016) emphasized the importance of play in reducing anxiety and negative emotions in hospitalized children.

Studies that were presented in literature mostly use observations and interviews with children (accompanied by parents) or sometimes only with children's parents, while a few uses art-based activities to actively engage with children. For instance, Coad and Coad (2008) investigated the viewpoints of young children regarding social spaces within hospitals to guide the design of the built environment of a new children's hospital through one-to-one semi-structured interviews and workshops accompanied by art-based activities. They found that children desire a variety of age-appropriate entertainment options that are easily accessible throughout the hospital. These activities not only combat boredom but also empower children with choices and reduce feelings of isolation by fostering social connections within the hospital community and beyond. Belver and Ullan (2011) presented a case study from a children's hospital in Spain focusing also on using art to improve the hospital environment as well as the emotional experiences of children; they conducted interviews with parents and other relevant healthcare professionals working in the hospital; however, no children were engaged in this one.

In another example by Lambert et al (2016) about social spaces for young children in hospital, the importance of using art to positively impact the children's emotional status was emphasized; additional to that, the authors brought up that technology can assist in expanding children's social connectivity during their hospital stay, bridging connections to home, school, and the larger world.

In respect to comparative studies, Cartland et al (2018) conducted research about the experiences of children (aged 3-17) admitted to a recently established facility tailored to promote child-centred care and equipped with family-friendly amenities, and those admitted to a prior facility lacking such accommodations through interviews. The newly constructed facility served as a replacement for the older establishment. In this example, the findings show that children in the new facility experienced less anxiety than in the old one; parents and children identified distinct aspects of the hospital that they deemed restorative.

4. The Service Design of Healthcare and Children's Needs

In the past ten years, there has been a growing focus on encouraging children and young individuals to actively engage and participate in decision-making processes and services that impact them regarding their health (Cartland et al., 2018; Coad et al., 2008). Even though literature points to the importance of involving children in the development such processes and services, practices vary. For instance, in a rehabilitation examination study by Miettinen and Alhansuo (2019), the participants of the study were mainly children's parents and healthcare professionals. In another study, Alhansuo et al (2023) discuss how children can be engaged in shaping hospital services through creative storytelling, how service design can be used to create innovative materials; data from these creative processes were analyzed to develop a fiction-based storytelling approach and visual service journey mapping tool for children's service design process in Finnish hospitals. Aldiss et al (2009) wrote about exploring children's experiences and views of cancer care services by using play and puppets for collecting data rather than interviews or observations. Using play and puppets could be connected to using storytelling as a method as in Alhansuo et al (2023).

What this literature research shows is, that in healthcare projects addressing children, parents are often still the main collaborators and if children are involved interviews are used more often than co-design activities, however there are increasing efforts specifically in service design projects, that emphasize play and storytelling as promising participatory design approaches. There is a lack of research into overarching objectives and qualities that social design can add to healthcare for and with children. As a response to this gap, the following research questions are explored in this study: What are the specific qualities and what is the value that social design can add to healthcare for and with children?

5. Research Methodology

This study uses case study as the methodological approach. Case study research entails a thorough and focused examination of a specific event, situation, organization, or social group (Yin, 2014).

Case study research offers the advantage of providing detailed data from various sources. However, opinions vary on the generalizability of case study outputs across different settings (George et al., 2005). By employing a qualitative case study approach, George et al (2005) emphasize the potential for a thorough examination of specific cases. From a design research perspective, Breslin and Buchanan (2008) describe case studies as exploratory and descriptive tools that not only construct phenomena but also contextualize them within relevant literature and discourse.

In this study three cases from healthcare design with and for children, developed in a social design master programme, MA Design for People, at Design School Kolding in Denmark are presented. The empirical data was acquired through various methods in each three cases: a) closely monitoring, and guiding student projects over five months, b) MA project reports, c) scrutinizing final presentations and design proposals of the student projects. The MA project reports consist of a relevant literature review, research methodology and methods used, as well as the final presentations which encompass both design proposals/solutions and comprehensive process mapping, highlighting different types of engagements, tools used, and findings for each project.

The methodology for analysing the three projects for distinct social design qualities is based on and inspired by Markussen's (2017) framework of social design. The framework defines aim, modus operandi, social value, locus of innovation and effect to clarify social design's main qualities. We use the three aspects modus operandi, social value and effect which we deem relevant for our case analysis. In regards to modus operandi, which translates to tools and methods, the framework states: "Co-design processes and material aesthetic practices take centre stage in the form of infra-structuring contradictory interests and resources"; with respect to social value it states: "Social value is conceived of as a small, but decisive qualitative change in the form of a re-distribution of identities or interpersonal relations."; in relation to effect it states: "Micro-scale effects that may reach a meso-level, but these effects rarely 'break out of their limited frame". (Markussen, 2017:169)

6. The Three Cases

The study explores three case studies from a master's programme focusing on social design and codesign in Denmark. The three case studies are covering various aspects of healthcare involving the creation of environments and experiences that promote healing, comfort, and a sense of safety for children and parents (Table 1). Case study 1 is the design of a set of sensory products to assist parents and nurses/bioanalysts in calming and reassuring their child during a blood test experience and reduce the child's needle phobia. Case study 2 is the design of a safe and playful spacious experience to reduce the level of anxiety in children before having a surgery. Case study 3 is the design of a dialogue tool and a peer-to-peer support service for parents of premature babies.

Table 1. An overview of the projects, analysis lens and the images from the design outcomes.

The case studies	Modus operandi/ Methods	Social value	The design outcome
A set of sensory products for calming children	Observations, sensory ethnography, semi-structured interviews, probes, workshops	More active roles for parents, Expanded roles for healthcare staff, fresh hospital identity	
A safe and playful spacious experience before having a surgery	Semi-structured interviews, digital workshops with children and parents	Advanced interpersonal relations between parents and children, Playful interaction between children in the same situation	
A dialogue tool and a peer-to-peer support service for parents of premature babies	Observations, Interviews Dialogue tools (Timeline, Privacy Mapping, Relationship Activity Chart)	New interpersonal relations between veterans and parents in the same situation	

Case study 1: the design of a set of sensory products to reduce the child's needle phobia for blood test

The first case we explore in this paper focuses on designing a set of sensory products to support parents and nurses/bioanalysts in calming and reducing the child's needle phobia for blood tests. It aims to address the issue of children's fear of needles during blood tests. It begins by observing blood tests in the children's ward of a Danish hospital to understand the child's perspective. Expert insights are gathered from various stakeholders including children, parents, pediatric nurses, bioanalysts, a play therapist, hospital clowns, design specialists, and a healthcare anthropologist. These first-hand experiences inform the project, guiding the development of supportive tools to enhance the pediatric blood test experience. The background of this project is rooted in the fact that needle pro-cedures are among the most feared experiences children have in healthcare (Kortesluoma & Nikkonen, 2004) and the importance of child-centred care as an approach within pediatric medicine that emphasizes the significance of placing the child's experience at the forefront of their care (Ford et al., 2018).

Figure 1. The different elements of the project, which translates to calmness and safety. Image credits: Roseanne Marie Kimber.

The outcome of the project was a set of sensory producs that parents and nurses/bioanalysts to prepare and support children for blood tests. These producst help to communicate psychological care through the senses. The products come in a kit with 3 tools and an infor-mation leaflet with images. The set of products can be used for preparation, sensory comparison, calming or hypnoanalgesia, a recognised technique for relaxation; they can be used in the waiting room in the time before the blood test when the child needs to wait 30minutes for the numbing cream to work as well as in the test room with the nurse/bio-analyst. (see:https://www.roseannekimber.com/work/sensorytoolsforreducingneedlefear).

Case study 2: The design of a safe and playful spacious experience to reduce the level of anxiety in children before having a surgery

The objective of the second case is to enhance the hospital experience for children by infusing with elements of playfulness and relaxation, thereby mitigating pre-operative anxiety. The study context was awaiting room in the children's department at a Danish hospital before children are taken to surgery. This initiative is rooted in the prevalence of perioperative anxiety and physical discomfort among children undergoing surgery, as documented in numerous studies; research indicates that preoperative anxiety can exacerbate postoperative pain, negative behaviours, and complications like delayed wound healing, delirium, and nightmares (Baghele et al, 2019). Factors contributing to this anxiety include fear of surgery,

separation from parents, unfamiliar surroundings, and loss of autonomy; the stress typically begins upon scheduling the operation and peaks upon admission to the hospital (ibid).

Figure 2. The different elements of the project which translates to playfulness and calmness. Image credits: Christina Sapounidou.

Recognizing the significance of addressing preoperative anxiety, this project seeks to leverage design strategies to create a more soothing and familiar environment for paediatrics patients. By incorporating elements that evoke feelings of calmness, comfort, and control, the aim is to alleviate stress and foster a sense of acceptance and security in an otherwise unfamiliar setting. Techniques such as non-pharmacological interventions, information dissemination, and distraction are explored as potential means to minimize preoperative anxiety and promote a safer and more positive surgical experience for children (Charana et al,2018).

The outcome of the project was an installation for children in a hospital's waiting area, which can be considered as an individual preparation for children; it is supposed to provide bodily physical calmness before children undergo an operation. It can be used by one child, siblings, children waiting for an operation at the same time or children and their parents. This spacious design consists of a seating area, a soft playful wall to lean on, touch or immerse the body into, another seating / laying on piece, and an interactive part to light up the space in different colours (Figure 2).

Case study 3: The design of a dialogue tool and a peer-to-peer support service for parents of premature babies

The third case study we explore in this paper focuses on designing for peer-to-peer support among parents of premature babies. The study context was a Neonatal Intensive Care Unit at a Danish hospital. The background of this project is the fact that in Denmark, around 4000 children are born each year prematurely (Dansk Præmatur Forening, 2020). Clottey and Dillard (2013) assert that these parents often experience a long and hard period of insecurity, not knowing whether their child or children will survive and whether it will be with or without a disability. This emotional distress can lead to parents feeling hopeless and powerless to a larger degree than parents of full-term babies' experience.

Figure 3. The different elements of the kit Samvær, which translates to socialising. Image credits: Marie Kremer.

The outcome of the project was a product-service solution, a kit that works hand in hand with peer-to-peer support led by so called veterans. These parents went through the experience of having a premature baby in the past and could therefore empathize with parents in the same situation. The kit includes a card congratulating the parents on the arrival of their child, activity cards that give the parents the option to choose what they would like to do during the meetings with the veterans, emotion objects, and a map and memory cards, which allow one to document and keep fond memories made in the hospital (see https://www.mariekremer.com/samvaer) (Figure 3). Introducing a kit with various tactile and material objects helps veterans and novices to structure and moderate their meetings and perhaps touch on what is close to the parents' hearts but not so easy to talk about.

7. Analysis

7.1 Modus Operandi/Methods: How the Projects Used a People-Centric/Patient-Centred Approach in the Process

In the first case, the focus was set on child-centred care (Ford et al, 2018) by investigating how to best support children to have less-anxious blood test experiences based on a participatory design approach. The research design consisted of the following steps: visits to the hospital, observations at the children's department in terms of blood test experiences, semi-structured interviews with several healthcare professionals and designers working in healthcare and focusing on children and a play therapist, participant observations as a clown, probes and an online 'Play Doctor Workshop'. The engagements with children (except for observations) were based on different joint actions such as dreaming, performing (dressing up and acting), imagining/dreaming, making, and reflecting (Figure 4).

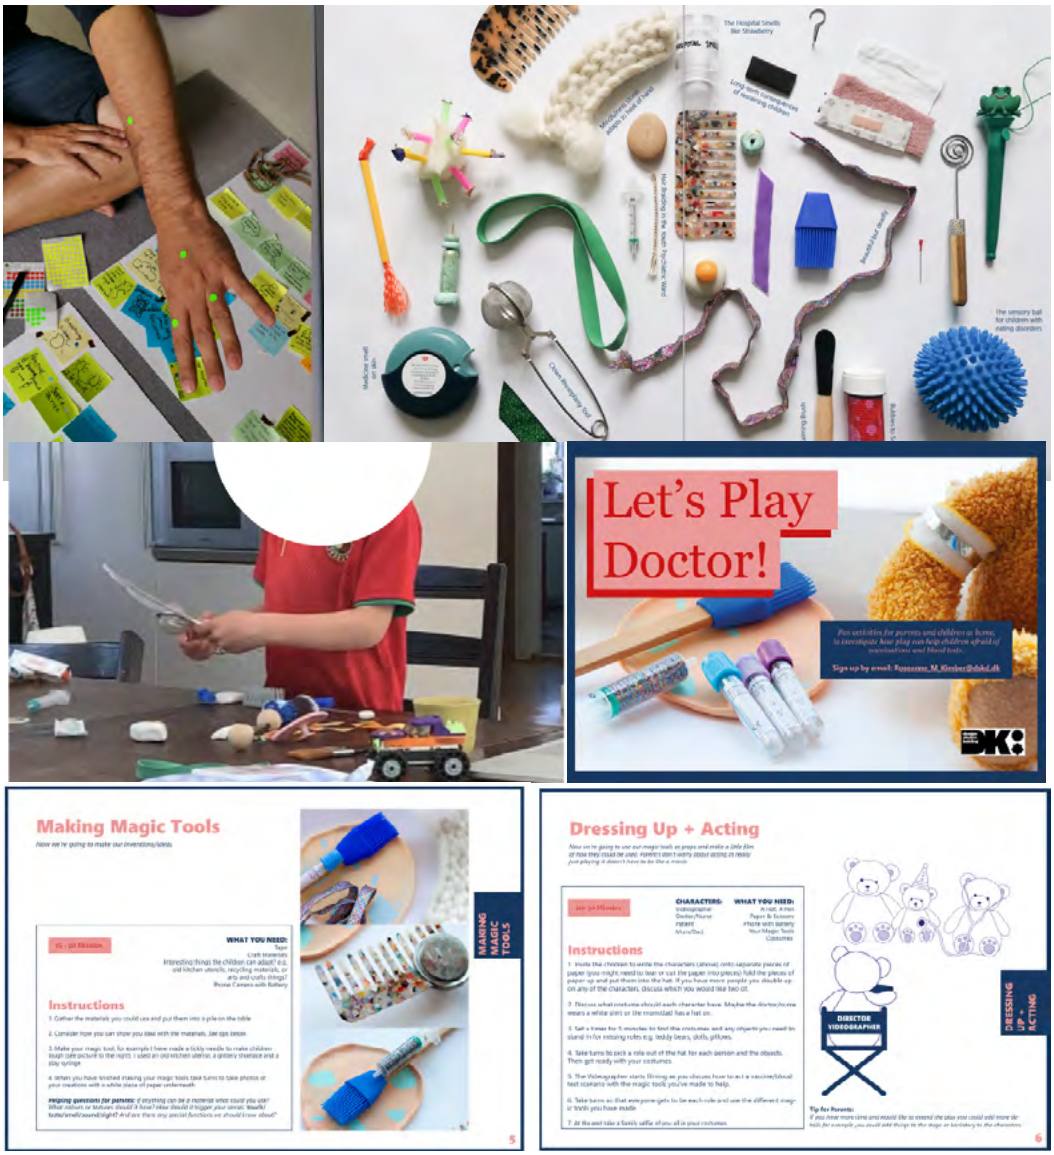

Figure 4. The different elements of the project, which translates to calmness and safety. Image credits: Roseanne Marie Kimber.

In the second case, the focus was on the anxiety levels of children in the pre-operative period at the hospital. The research design consisted of the following steps: visits to the hospital, interviews with nurses working in the children's department in different hospitals, one physical and three online workshops with children (together with a parent if the child was at an age that required adult companionship).

As depicted in the images below, in these workshops the design researcher used drawing as a a means to imagine what children would pack in a fictional suitcase to be as well prepared as possible for their hospital stay and surgery as well as what made them feel calmer and which character lived there among the provided images. In another workshop, different materials were used to involve children (and their parents) in co-designing the actual design proposal.

Figure 5. The different elements of the project which translates to playfulness and codesigning. Image credits: Christina Sapounidou.

In the third case, throughout the project, a focus was set on emotions and feelings of the parents, which shaped the participatory design approach. The research design consisted of the following steps: Observations at the neonatal intensive care unit (NICU), interviews with medical staff that were carried out to draw on the staff's expertise on how to support parents and to help place the individual parents' stories in a broader framework. Interviews with parents explored their challenges and feelings in the NICU and to provide a platform to share their stories. Based on these insights the designer worked with online workshops, using dialogue tools to generate knowledge and insights together.

The three tools (Figure 6) featured timeline (below) in which participants were asked to map out both the timeline of how their friendships developed and the progress of their hospital stay. The goal was to see if there were similarities between the two; a map of the ward where participants were asked to mark to where they felt safe and had privacy and where they did not. And lastly an activity chart in which participants were asked to outline the relationship they have with their friends, their activities, and

conversational topics and opinions that connect them. Here the designer wanted to find out whether there was a difference between friends inside and outside the hospital.

Figure 6. The different elements of the kit Samvær, which translates to socialising. Image credits: Marie Kremer.

7.2 Social Value: How the Projects Fostered a Re-Distribution of Identities or Interpersonal Relations

The set of sensory products for blood tests supports children in going through the pro-cedures that are among the most feared experiences they have in healthcare. Focusing on what is most feared and easing this experience ideally has dripple-down effects on the overall feelings that children have towards healthcare and thus can change the identity of the hospital as such. The set of tools also offer chances for a circulation of roles: parents can become a more active character when using the tool and thus support the healthcare staff in performing their procedures they have to do. Healthcare staff on the other hand can shift their role from a purely technical, medical one to a more child-centred caretaker act. In that way parents and healthcare form a new team and new interpersonal relations.

The playful installation introduced in case study two, suggests an alternative to common pre-operative waiting areas, not designed for children's needs in mind. By offering convivial, joyful materials, tactile structures and elements that spark curiosity, interpersonal relations between different parties are advanced. First and foremost, between parents and their children, which are given autonomy and choices between relaxation, withdrawal, or physical activity; and second it gives room for playful interactions between children in the same situation. Finally, also here, the hospital gains new options for a child-centred care identity.

Shared experience and an understanding of what others encounter are the foundation of peer-to-peer support (Hall et al. 2015). The suggested Veteran Parent System from case study 3 builds upon this finding and uses the principle of sharing for common good. New interpersonal relations can grow between those who went through the often-traumatizing process of being at the NICU with a premature baby and those in

the same situation. The reciprocal nature of the service implies that parents can take on different roles and thus re-distribute their identities – recipients of the service can become veterans with the possibility to give back and pass on their experience.

The system introduced in case study 3 creates a protected space for parents with the hospital as the distributor of the new service. In this sense also the hospital changes its identity by offering a service that goes beyond the purely medical one, acknowledging that feeling safe and understood supports the wellbeing of the parents and thus in return their premature baby.

8. Discussion and Conclusion

Based on the analysis of the modus operandi of the case studies and their social values we would like to discuss the specific qualities and values that social design can add to healthcare for and with children. What future social designers should be cautious about when designing healthcare with/for children are the following points:

Encourage young patients' and their parents' agency: Designers endeavour to encourage young patients' and their parents' agency by designing experiences that foster engagement, education, and pro-active participation in their own well-being. This includes creating tools, interfaces, and environments that facilitate a better understanding of health information and encourage proactive health management with a special eye on the needs of children and their parents. Social designers work in this way by working with tactile qualities, understanding through bodily experiences and performances, through touch, sound, and different materiality.

Increased engagement: The analysis of the cases suggests that social design leads to engaging young patients actively in their own care by designing experiences that encourage and educate them. This might involve user-friendly interfaces for medical devices, clear communication of health information, and tools that encourage participation in treatment plans as well as spacious experiences and overall services. Having an empathic approach, working closely and continuously with patients throughout a project process increases engagement, tends to create commitment and ownership for patients and their parents as well as related healthcare professionals.

Foster a sense of well-being: Social designers aim to create environments that promote a sense of calm, comfort, and well-being for young patients and their parents. Factors like lighting, colours, furniture, and overall spatial design can significantly impact the emotional state of patients during their healthcare journey.

Enhance patient satisfaction: Social designers aim to elevate patient satisfaction by addressing not just the medical treatment but the entire journey within healthcare facilities. This includes considering aspects such as waiting times, ease of navigation, and emotional support during the healthcare process.

For social designers and healthcare designers, this paper contributes a set of three examples, detailing four design objectives that might enhance the agency of children when navigating through healthcare systems. To conclude, this paper suggests that a social design-led approach to healthcare for children working closely and continuously with patients throughout the project, could assist in creating value-driven services and thus increase the overall quality of care.

About the Authors:

Canan Akoglu works as Associate Professor at the Lab for Social Design and Head of Design for People Master's Programme at Design School Kolding. Her research and teaching experience covers designerly ways of engaging with stakeholders, service design and critical design that contribute to fostering agency and citizenship in everyday life.

Kathrina Dankl is an associate professor at the Lab for Social Design where she focuses on experimental methodologies for an active involvement of various stakeholders in the design process, supporting agency, democratic participation, and active citizenship.

Acknowledgements: We would like to thank Design for People Master's Programme Graduates Roseanne Marie Kimber, Christina Sapounidou and Marie Kremer very much for sharing their MA Project work and all the details with us.

KEYWORDS | SPECULUM, HISTORY, REDESIGN, COMFORT, MEDTECH, FEMINIST DESIGN, PERCEPTION

ABSTRACT | The history of the speculum is primarily characterized by the stigmatization of the female body and unethical behavior towards people with vaginas. Despite its long history of use in gynaecology, routine examination with this instrument remains uncomfortable for many patients. This paper takes a feminist perspective to open up new approaches to design in medical settings. It examines the influence of social gender on the perception of individuals and the role of gender stereotypes. Through an analysis of medical, sociological and bioethical texts as well as surveys and interviews with patients and professionals, the need for a redesign of the speculum is highlighted. A market analysis and comparison with other concepts show realistic possibilities for a redesign. The results emphasize the increasing importance of comfort for patients in medical examinations and also show that changes in this area must be achieved not only through new products, but also through structural changes.

1. Introduction

The speculum is an instrument that is known and used by almost every person with a vagina. It is used as an examination instrument in gynaecology and is utilized in every routine examination to take a swab of the vaginal tissue as well as that of the cervix (Wright et al., 2004). From the first penetrative sexual intercourse until after menopause, this instrument is typically used once a year for every person with a vagina (Barad, 2021).

The speculum is one of the earliest instruments used in gynaecology and has thus shaped the development of this medical specialty (Baker, 1999). However, the instrument not only reflects developments in medicine but also society's attitudes, values, and perceptions of the female body. In addition to analysing the product, this thesis also considers the speculum as a symbol that reflects and questions social, gender-specific, and cultural dynamics.

The current state of medical research primarily involves identifying issues with the speculum's usage and exploring how these can be addressed by increasing awareness among healthcare providers. This work draws on studies such as “Improving women's experience during speculum examinations at routine gynaecological visits: randomized clinical trial” (Seehusen et al., 2006), and “A comparison of two techniques for vaginal speculum placement to reduce patient pain” (Pérez et al., 2021). Both studies highlight an awareness of the needs of those undergoing examination, yet they also reveal persistent comfort issues. It seems that raising the awareness of those providing treatment is the only way to better meet the needs of the people being treated.

As the speculum is to be analysed from multiple perspectives, contributions from the social sciences, the book “Unbehagen der Geschlechter. Gender Studies” (Butler, 1991) and other contributions to gender studies are consulted. These are essential for understanding the social, societal and cultural background of the instrument. This literature elucidates social constructs and concepts that continue to influence us today. While the speculum has proven its efficacy as a gynaecological instrument, it is noteworthy that there has been surprisingly little innovation in its design, considering its central role in medical examinations.

Papers and articles that reflect a redesign of the instrument, such as “An Innovative Design for the Vaginal Speculum” (Bouquet et al., 2023), are also considered. These show what possibilities exist for a redesign. At the same time, they highlight the limitations of developing a new tool. Those limits are primarily characterized by competition from existing products on the market, due to their price efficiency and longevity.

To clarify the significance of the speculum, it is necessary to analyse its historical evidence and archaeological finds. The historical analysis illustrates the relevance of the topic, but also shows the stigmatization of the speculum by sources such as (Heinesohn, Steiger, 1987). Other historical sources, like (Ojanuga, 1993), delve into the intersection of medicine and the social sciences, examining the ethics of instrument development and questioning its impact on the modern instrument.

Addressing the issue of sensitive design, particularly concerning the speculum, implies an awareness of the needs of the individuals undergoing treatment. A plausible conclusion should be that there is a wide range of different tools available for the treatment. However, this is not the case. That's where this paper picks up by analysing the approaches from different fields, bringing them together and designing an interface where a new instrument can emerge.

In particular, the position of the person undergoing examination hardly seems to be addressed as a factor for a redesign. The following question is therefore used as a guiding research question to identify those aspects that are useful for a redesign:

How can the need for comfort be reconciled with the practicalities of everyday examinations? Is this even feasible?

The summary of the state of research places the development and current status of vaginal speculum in the context of gender studies, the social sciences and medicine. A historical analysis clarifies the emergence of the speculum and helps to understand its impact on modern gynaecology. This analysis highlights the urgency of redesigning the instrument to respond to the changing needs of patients.

Another methodological approach is the application of the theory of the symbol (Hülst, 1999), which abstracts the speculum as a symbolic object. It represents both the problems and challenges in the development of the instrument due to historical, cultural and social structures as well as the possibilities for change and redesign.

In addition to these theoretical approaches, practical methods were applied. These include interviews with gynaecologists to gain insights into their perspectives and experiences. Furthermore, surveys were conducted among people with vaginas of different age groups (18- 54) to capture their perceptions of the examination experience and the instrument and to collect potential suggestions for improvement. Moreover, shape analyses are conducted to elucidate the shape and function of both the speculum and the vagina. An integral aspect of the argumentation involves the prototype currently under development. This is aimed at enhancing the examination experience for all patients, with particular emphasis on addressing special needs of patients. Additionally, the prototype should serve educational purposes to bridge the gap between specialists and non-specialists, as well as to combat the stigmatization of the female body.

The aim of the redesign is to develop an instrument that not only enhances comfort for patients but also provides relief for medical personnel. By prioritizing increased comfort, additional specific objectives that cannot be fully achieved with the current state can be pursued. Integration of technologies can facilitate quicker detection and documentation of diseases and abnormalities. Furthermore, the redesign can lead to patients having fewer concerns about the examination, attending appointments more regularly and diseases being diagnosed more efficiently. This contributes to both patient well-being and potential relief for the healthcare system. Through a needs-oriented redesign of the product, accessibility for individuals with specific needs can be enhanced.

This paper is part of my ongoing master's thesis, that’s why it’s not always mentioned as a paper.

This paper is structured as follows: An excursus into gynaecology and the anatomy of the female body clarifies the topic and locates the speculum as an examination instrument in gynaecology. The design of the current specula is derived from the historical development of this examination instrument.

The following chapter deals with gender-specific perception and the role it plays in the development of specula. The design is strongly influenced by social and cultural dynamics from the time the instrument was created. This imprint still strongly influences the perception of the speculum during the examination. The following section discusses how the speculum's design can influence its perception on a deeper level and how this can be steered in a more positive direction.

Finally, a “requirements profile” is developed through comparisons with new approaches to different specula and other medical fields, which provides a framework for redefining this instrument.

The challenges encountered when redefining and reinterpreting a product in this manner are addressed.

2. The Speculum as an Instrument in Gynaecology

The speculum is a medical instrument that provides insight into various body orifices through its spreading function. The vaginal speculum opens the vagina by insertion and provides a view of the cervix (lowest point of the uterus). Vaginal specula are used in gynaecological examinations to take sterile swabs from the vagina and cervical tissue. In some cases, the speculum is used to insert other instruments sterilely through the vagina into the uterus (Speculum, n.d.).

Specula are available in metal, which are cleaned and sterilized after use, and plastic, which are designed for single use. The latter are primarily used in hospitals. The speculum is also available in various sizes and designs, depending on the preference of the person performing the procedure and the circumstances in which the speculum is used.

2.1 Form and Function

The shape of the speculum has been developed in close relation to the anatomy of the vagina. The vagina is a hollow organ (Jung, 2023). It is a hollow, muscular tube that connects the external genitalia to the uterus. The anatomy of the vagina dictates the construction of the speculum, requiring it to be elongated and narrow to adequately open the entire length of the vagina. Due to the elasticity of the vagina, it can expand and contract to many times its own size, which is necessary for childbirth. In its contracted state, often considered the initial position, the vagina exhibits numerous invaginations and indentations. Certain factors influence the shape of the vagina and the resulting functions of the speculum. Very young patients are often more sensitive to the pressure of the instrument, which is why smaller specula are particularly advantageous. Shortly after giving birth, the tissue is still very stretched, which means that more tissue has to be displaced during subsequent vaginal examinations. As soon as menopause occurs, the vagina changes again and becomes less flexible and therefore more sensitive again due to the absence of oestrogen (Falco, 2021).

The examples of organic changes in the vagina influence both the choice of material and the shape of the speculum.

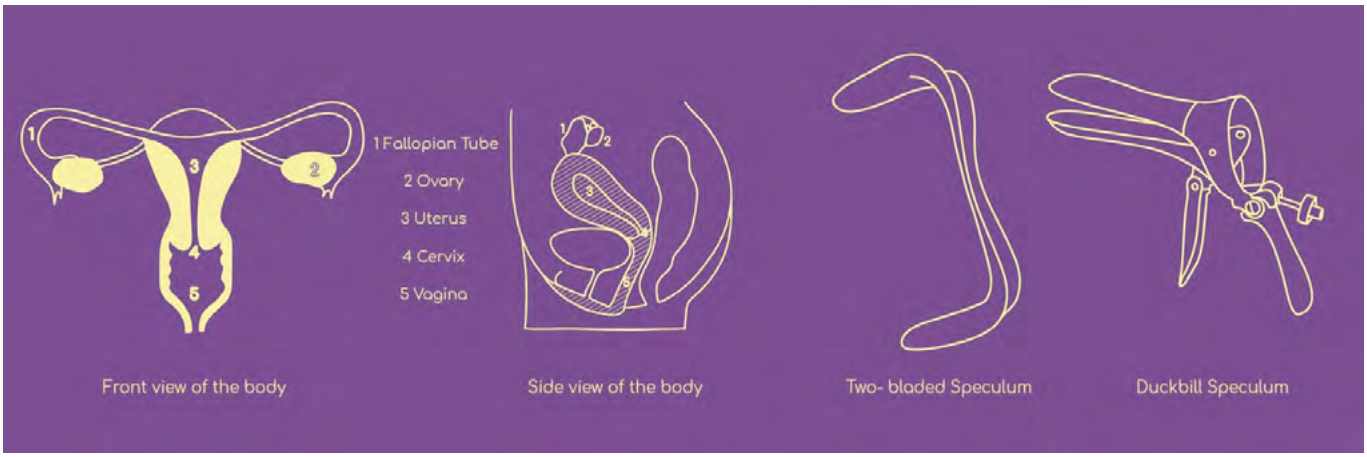

Figure 1. Shows the vaginal structure from the front and side and the gynaecological Speculum in the most common variations nowadays.

The instrument must be able to displace tissue (Pardes, 2017). How much and how strongly depends on the anatomical conditions. For example, obesity exerts particularly high external pressure on the vagina (Palsgaard et al., 2022). This functional requirement, as well as the necessary sterilizability, led to steel being preferred over wood as a material over time (Spekulum aus Holz, n.d.). Steel is not only robust, but it's also easy to clean and, with the right care, durable.

There are different variants of the shape of the speculum (Spekulum aus Holz, n.d.). There are specula with one, two or more blades. Typically, the speculum we are most familiar with is the duckbill speculum, which has two blades (see Illustration). The duckbill speculum is available for one-handed operation, which makes it particularly suitable for use in everyday practice. The instrument can be secured with a screw after opening and sits securely in the vagina so that the practitioner can carry out the examination and swabs. Another variant of the speculum is also used in everyday practice, but more frequently during surgical procedures. This speculum consists of two individual parts (more likely to the two- bladed speculum in the Illustration) and must be held in place throughout the procedure, which requires the presence of another person.

2.2 Procedure of Examination with the Speculum
